May 2023

ADF\&G Fishery Data Series was established in 1987 for the publication of Division of Sport Fish technically oriented results for a single project or group of closely related projects, and in 2004 became a joint divisional series with the Division of Commercial Fisheries. Fishery Data Series reports are intended for fishery and other technical professionals and are available through the Alaska State Library and on the Internet: http://www.adfg.alaska.gov/sf/publications/. This publication has undergone editorial and peer review.

Product names used in this publication are included for completeness and do not constitute product endorsement. The Alaska Department of Fish and Game does not endorse or recommend any specific company or their products.

#### Abstract

The Alaska Department of Fish and Game, Division of Sport Fish has used a weir to assess the annual runs of coho salmon (Oncorhynchus kisutch) to the Buskin River on Kodiak Island since 1985. This report presents weir counts, harvest, and age-composition data collected for 2018 and 2019. In 2018, the inriver run estimate was 4,523 fish; the estimated sport and subsistence harvests were 1,793 fish and 1,171 fish, respectively, and the commercial harvest was zero. The estimated escapement was 4,164 coho salmon. Age- 2.1 fish composed an estimated $78.9 \%$ of the inriver run and the male-to-female ratio was 2.4 :1. In 2019, the inriver run estimate was 5,537 fish; the estimated sport and subsistence harvests were 934 fish and 340 fish, respectively, and the commercial harvest was zero. The estimated escapement was 5,350 coho salmon. Age- 2.1 fish composed $52.3 \%$ of the inriver run and the male-to-female ratio was 1.1:1.

Keywords: coho salmon, Oncorhynchus kisutch, escapement, Buskin River, age-sex-length composition, sport harvest, subsistence harvest, stock assessment

## INTRODUCTION

The Buskin River drainage, located on the northeast end of Kodiak Island (Figure 1), contains one of the largest wild populations of coho salmon (Oncorhynchus kisutch) found on the Kodiak road system. It is the most popular recreational fishing stream on the island, representing $29 \%$ (recent 10-year average) of the total freshwater sport fishing effort in the Kodiak Regulatory Area (Alaska Department of Fish and Game [ADF\&G] Statewide Harvest Survey ${ }^{1}$ ). Sport fishing effort on the Buskin River is directed primarily toward coho and sockeye salmon (O. nerka), but some effort is also directed at steelhead and rainbow trout (O. mykiss), pink salmon (O. gorbuscha), and Dolly Varden (Salvelinus malma). From 1989 through 2017, estimated sport harvests of coho salmon from the Buskin River ranged from 1,474 fish to 6,567 fish and averaged 3,438 fish (Table 1 and Figure 2).

The Buskin River drainage also supports the largest reported subsistence coho salmon fishery in the Kodiak Archipelago, which takes place in salt water directly adjacent to the mouth of the river. Buskin River coho salmon typically compose about $20 \%$ of the total Buskin River subsistence salmon harvest, with reported harvests ranging from approximately 287 fish to 2,414 fish and averaging 1,288 fish from 1989 through 2017 (Table 1). Harvest in this fishery is documented through subsistence permits issued by the ADF\&G Division of Commercial Fisheries (CF).

A relatively minor commercial harvest of Buskin River coho salmon occurs periodically in adjacent marine waters of Chiniak Bay. These harvests are typically small and during some years, nonexistent. Fish ticket harvest receipts available from CF Westward Region Fish Ticket Database indicate that between 1989 and 2017, the average annual commercial harvest of Buskin River coho salmon was 79 fish (Table 1).

Buskin River coho salmon runs have been monitored since 1985 at a salmon counting weir operated annually by ADF\&G; the weir has been in its current location since 1989, approximately 2 km above the mouth (referred to as the "lower weir"; Figure 1). Results from weir counts at the lower weir are presented in this report (Appendices A1 and A2). A second weir, located at the outlet of Buskin Lake (referred to as the "lake weir"; Figure 1), monitored coho salmon runs annually from 2009 to 2017 and was used to estimate escapement for those years. The goal of the weir monitoring program is to ensure the sustainability and long-term health of the stock through

[^0]continued refinement of the escapement goal as more brood year returns are assessed. Between 1989 and 2017 (excluding 2015), the average lower weir count was 8,843 coho salmon, and counts have ranged from 2,513 to 16,596 fish (Table 1). In 2016, the lower weir count fell below the escapement goal of 4,700 coho salmon. Weir counts of adult fish entering the Buskin River are obtained from early August through the end of September, with peak daily counts of coho salmon typically occurring during the third week of September.

The Buskin River coho salmon escapement goal is based on a spawner-recruit model that uses escapement and age composition estimates provided by this project along with sport, subsistence, and commercial data collected by the programs described above. The current coho salmon escapement goal range of 4,700-9,600 fish was established as a biological escapement goal (BEG) in 2013 using a Ricker stock recruitment model (Ricker 1954; Fleischman et al. 2013; Sagalkin et al. 2013) and was changed to a sustainable escapement goal (SEG) with the same range in 2019 (McKinley et al. 2019). The escapement goal directs inseason management of the sport, subsistence, and commercial fisheries. Periodic refinement of the escapement goal is possible through continued collection of required data by this project and the sport, subsistence, and commercial harvest programs. This report presents estimates of Buskin River coho salmon spawning escapement, age composition, and sport, subsistence, and commercial harvests for 2018 and 2019.

Note: Inriver run is the sum of upriver sport harvest and escapement.

## OBJECTIVES

The objectives of the 2018-2019 stock assessment of Buskin River coho salmon were as follows:

1) Census the coho salmon inriver run at the lower Buskin River weir from August 1 to September 30 each year.
2) Estimate the age, sex, and length (ASL) composition of the coho salmon run.

## METHODS

## InRIVER RUN

A floating weir, operated at the lower weir site (Figure 1), was constructed across a channel approximately 40 m wide where the predominantly small rock substrate was suitable for anchoring a weir. The weir was constructed of 2.54 cm , schedule-80 PVC (polyvinyl chloride) pickets connected by riveted rubber straps to form panels approximately 1.6 m wide by 3.3 m long. Panels were connected via a single picket and anchored to the substrate via webbing connected to 2.86 cm chain. Steel pipe posts were driven into the substrate through the overlapping chain links from each panel to provide additional anchoring. To provide additional floatation, polyform L-3
buoys were attached to wooden boards approximately 3 m long. The boards were attached to the panels via bungee cords and placed underneath the downstream side of the panels; this design allowed the weir to float with minimal drag in changing water levels. Two counting gates were used to pass fish, and a trap constructed of aluminum panels, with a funnel-shaped entrance and attached to a counting gate, was installed to capture immigrating coho salmon for sampling (Figure 3).

During each year, the lower weir was monitored daily from the beginning of August through the end of September. Fish passage through the weir was only allowed when counts were made; all immigrating and emigrating anadromous fish were enumerated and identified by species. The lower weir was designed to operate continuously; however, during 2018 and 2019, a portion of the inriver run was estimated, when high water levels precluded the controlled passage of fish. Estimates of coho salmon passing the lower weir during periods of high water were calculated using a variety of methods (Table 2). As a result of periodic interruptions in lower weir counts from high water events and variability in the annual duration of weir operations, the weir counts presented in any given year should be considered an estimate (not a census) of the inriver run, and this estimate should not be considered the escapement because sport fishery harvest of coho salmon occurs upstream of the lower weir.
After removal of the weir, 1 postseason foot survey of the Buskin River was conducted to estimate the number of fish that entered the river after the weir was removed. If a flooding event was not in the forecast and water levels and water clarity were favorable, the postseason foot survey would take place below the weir site immediately after the weir was removed. The number of observed fish would be added as a postseason estimate. If the weir was removed immediately prior to a flooding event, the survey occurred when river conditions were improved (this could take several days), and the entire river was surveyed once to obtain an estimate of the number of fish within the watershed. The difference between the postseason foot survey estimate and weir count would be added as a postseason estimate.

Figure 3.-Buskin River lower weir with counting gates and sampling trap.

|  |  | Total | 4.5 | 2,134 | 47.2\% |  |
| 2019 | 31 Jul-1 Oct | Postseason | 0 | 500 | 9.0\% | Based on a postseason foot survey. |

## Fishery Harvests

Annual subsistence harvests of Buskin River drainage coho salmon were estimated from returns of subsistence fishing permits received by the CF Kodiak Office. From 2008 through 2019, annual return rates of permits ranged between $82 \%$ and $93 \%$ and averaged $87 \%$ (CF Westward Region Subsistence Database). It was not possible to estimate the proportion of permit holders harvesting Buskin River coho salmon who failed to return permits.
The Statewide Harvest Survey (SWHS) estimates the participation, harvest, and catch of sportcaught species by area and by fishery (Romberg et al. 2020). The sport fishery harvest of Buskin River coho salmon in 2018 and 2019 was estimated by the SWHS. Harvest that occurs above the lower weir is assumed to be $20 \%$ of the total SWHS estimate for the Buskin River, based on a creel survey conducted by Murray (1987).
Commercial harvests were obtained from the CF Statewide Harvest Receipt (fish ticket) database. Reported catches of coho salmon from only ADF\&G Kodiak Salmon Statistical Chart ${ }^{2}$ areas 259-22 and 259-26 (Womens Bay statistical area and Buskin River Section) were assumed to be of Buskin River origin.

## Age, Sex, and Length Composition Sampling

Coho salmon were sampled for ASL data from the 2018 and 2019 inriver runs. The sampling period was stratified into three 2-week intervals between August 16 and September 30. Whenever possible, all coho salmon captured in the weir trap were sampled. Sampling was typically conducted 3-4 days per week. Sport, subsistence, and commercial harvests were not sampled for ASL composition, and samples from the inriver run were used as proxies for each of these run components.

Length from mid eye to tail fork (METF) was recorded to the nearest millimeter for each sampled fish, and sex was determined from external characteristics. Whenever possible, 4 scales were removed as described by Welander (1940). Sampled scales were taken from the preferred area on the left side of the fish, 2 scale rows above the lateral line, and placed on a gum card for subsequent analysis. Scales not available from the preferred area were taken in the same linear plane but from the third or fourth row below the lateral line. If it was not possible to take scales from the left side of the fish, scales were collected from the opposite side in the same manner as described above. Ages of sampled coho salmon were determined from scales using criteria described in Mosher (1969).

## Data Analysis

## Total Run and Escapement

The number of coho salmon in the total run $\left(\widehat{N}_{T}\right)$ for each calendar year $T$ was estimated by

$$
\begin{equation*}
\widehat{N}_{T}=\widehat{S}+H_{S u b}+H_{C F}+\widehat{H}_{S F} \tag{1}
\end{equation*}
$$

where $\widehat{S}$ is estimated escapement, $H_{S u b}$ is subsistence harvest, $H_{C F}$ is commercial harvest, and $\hat{H}_{S F}$ is estimated sport harvest. Subsistence and commercial harvests were assumed known with zero

[^1]variance, whereas $\widehat{H}_{S F}$ and its variance were provided by the SWHS. Because sport fishery harvest of coho salmon is not reported by area within the Buskin River drainage, and harvest occurs downriver and upriver of the weir, escapement was estimated as follows:
\[

$$
\begin{equation*}
\widehat{S}=W-(1-\rho) \widehat{H}_{S F} \tag{2}
\end{equation*}
$$

\]

where $W$ is the inriver run, as measured at the weir, and $\rho$ is the proportion of the sport harvest occurring below the weir. We assumed a value of 0.8 for $\rho$ (Murray 1987). It is recognized that the true value of $\rho$ may vary annually, but the introduced bias was not expected to be large; there was about a $6 \%$ increase in escapement estimates associated with 2008 through 2016 if a value for $\rho$ of 0.9 versus 0.8 was used, and a $7 \%$ decrease if a value for $\rho$ of 0.7 versus 0.8 is used.
The variances of $\hat{S}$ and $\hat{N}_{T}$ were estimated as follows:

$$
\begin{equation*}
\operatorname{var}(\widehat{\mathrm{S}})=(1-\rho)^{2} \operatorname{var}\left(\widehat{H}_{S F}\right) \tag{3}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{var}\left(\widehat{N}_{T}\right)=\operatorname{var}\left(\widehat{H}_{S F}\right) \rho^{2} \tag{4}
\end{equation*}
$$

## Exploitation Rate

The exploitation rate $\left(\hat{\mu}_{i}\right)$ for fishery $i$ was estimated as follows:

$$
\begin{equation*}
\hat{\mu}_{i}=\frac{\widehat{H}_{i}}{\widehat{N}_{T}} \tag{5}
\end{equation*}
$$

where $i$ is $S u b, S F$, or $C F$ for the subsistence, sport, or commercial fishery, respectively. For the subsistence or commercial fishery, the variance of the exploitation rate was estimated (delta method; Seber 1982: p. 8) as follows:

$$
\begin{equation*}
\operatorname{var}\left(\hat{\mu}_{i}\right)=H_{i}^{2} \frac{\operatorname{var}\left(\hat{N}_{T}\right)}{\hat{N}_{T}^{4}} \tag{6}
\end{equation*}
$$

where $i$ is $S u b$ or $C F$.
For the sport fishery, the variance of the exploitation rate was estimated (delta method) as follows:

$$
\begin{equation*}
\operatorname{var}\left(\hat{\mu}_{S F}\right)=\frac{\left[W+H_{S u b}+H_{C F}\right]^{2} \operatorname{var}\left(\hat{H}_{S F}\right)}{\left[W+H_{S u b}+H_{C F}+\rho \hat{H}_{S F}\right]^{4}} \tag{7}
\end{equation*}
$$

Total exploitation rate was estimated as follows:

$$
\begin{equation*}
\hat{\mu}_{T}=\frac{\sum_{i=1}^{3} \hat{H}_{i}}{\hat{N}_{T}} \tag{8}
\end{equation*}
$$

where $i$ is $S u b, C F$, or $S F$, with variance estimated by simulation.

## Age-Sex Composition

## Estimation

Although daily weir counts exist for the inriver run, no overall time-stratified estimate of the agesex composition of the total run was possible because the sport and subsistence harvests were not available by temporal strata.

The proportions ( $\hat{r}_{j}$ ) and variances of age or sex class $j$ for each run were estimated from the inriver run samples taken in 2018 and 2019, respectively:

$$
\begin{equation*}
\hat{r}_{j}=\frac{n_{j}}{n} \tag{9}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{var}\left(\hat{r}_{j}\right)=\frac{\hat{r}_{j}\left(1-\hat{r}_{j}\right)}{n-1} \tag{10}
\end{equation*}
$$

where

$$
n_{j}=\text { the number of coho salmon in the sample for a particular year that were in age or sex }
$$ class $j$, and

$n=$ the number of coho salmon sampled in that particular year.
No finite population correction factor was used because it would have been close to 1.0 (population size much greater than sample) and there was uncertainty in the total run because the sport harvest was estimated and flooding periodically compromised the weir count.

The number of coho salmon of age or sex class $j$ in the population of interest $i$ (where $i$ is $S, W$, $S F, S u b, C F$, or $T$ ) and its variance were estimated as follows:

$$
\begin{equation*}
\widehat{N}_{i j}=\widehat{N}_{i} \hat{r}_{j} \tag{11}
\end{equation*}
$$

with variance estimated (Goodman 1960) as

$$
\begin{equation*}
\operatorname{var}\left(\widehat{N}_{i j}\right)=\widehat{N}_{i}^{2} \operatorname{var}\left(\hat{r}_{j}\right)+\hat{\mathrm{r}}_{j}^{2} \operatorname{var}\left(\widehat{N}_{i}\right)-\operatorname{var}\left(\hat{r}_{j}\right) \operatorname{var}\left(\widehat{N}_{i}\right) \tag{12}
\end{equation*}
$$

## Length

Mean length-at-age and its standard error were estimated for each age class of the run (Cochran 1977: Chapter 2).

## RESULTS

It is important to note that the standard errors reported below for spawning escapement, total run, exploitation rate, and run by age and sex do not account for error in the estimation of the weir count when flooding occurred.

## 2018 SEASON

## Total Run, Harvest, and Escapement

The lower weir was tended from August 1 through October 8. High water conditions (flooding) interrupted operation of the lower weir twice, from August 18 through August 21 and on October 2 (Table 2). For the first event, 500 fish were added to the weir count and zero fish were added for the second event; these numbers were based on expansion of the weir counts just prior to the floods. A postseason foot survey of the Buskin River was conducted below the weir site to count fish, and this added an estimated 1,634 fish to the escapement count. The inriver run (lower weir count plus flood-period estimates and postseason survey estimate) of coho salmon in the Buskin River for 2018 was 4,523 fish, of which approximately $47 \%$ was estimated (Tables 1 and 2, Appendix A2).

In 2018, anglers fishing the Buskin River drainage caught an estimated 3,080 coho salmon and harvested 1,793 coho salmon, expending 9,471 angler-days of effort (Table 1). The reported coho salmon subsistence harvest was 1,171 fish, and the commercial harvest of Buskin River coho salmon was zero fish. The estimated spawning escapement was 4,164 coho salmon (SE 110). The estimated total run was 7,128 coho salmon (SE 440).

## Exploitation Rate

The estimated subsistence exploitation rate in 2018 was $16.4 \%$ (SE $1.0 \%$ ) and was substantially lower than the sport exploitation rate of $25.2 \%$ (SE $6.2 \%$ ); the commercial fisheries exploitation rate was zero, making the 2018 total estimated exploitation rate $41.6 \%$ (SE 5.3\%; Table 3).

Table 3.-Estimated exploitation rates (percent of total run) of Buskin River coho salmon subsistence, sport, and commercial fisheries, 2018 and 2019.

| Year | Statistic | Subsistence <br> fishery (\%) | Sport fishery <br> $(\%)$ | Commercial <br> fishery (\%) | Total (\%) |
| :--- | :--- | ---: | ---: | ---: | ---: |
| 2018 | Exploitation rate | 16.4 | 25.2 | 0.0 | 41.6 |
|  | SE | 1.0 | 6.2 | 0.0 | 5.3 |
|  |  |  |  |  |  |
| 2019 | Exploitation rate | 5.1 | 14.1 | 0.0 | 19.2 |
|  | SE | 0.2 | 4.5 | 0.0 | 4.4 |

## Age, Sex, and Length

A total of 98 coho salmon were sampled for sex and length from the inriver run, of which age was determined for 90 samples (Table 4). The run accounted for an estimated $78.9 \%$ age- 2.1 fish and $13.3 \%$ age-1.1 fish. Males represented $70.4 \%$ of the run, giving a male to female ratio of 2.4:1. There was no significant difference in length between males and females ( $Z=1.13, P=0.26$ ).
Comparison between the distribution of the age-sex-length sampling to the lower weir counts in 2018 shows the ASL sample was not well distributed with respect to the weir counts (Figure 4).

Note: Some fish may be sexed but not aged and vice versa. An en dash indicates the statistic is not applicable.

## 2019 SEASON

## Total Run, Harvest, and Escapement

The lower weir was tended from July 31 through October 1. Emergency orders were issued in September 2019 closing Buskin River coho salmon for subsistence, sport, and commercial fishing; however, increased escapements resulted in the emergency orders being rescinded about 2 weeks later. No flooding interrupted operation of the lower weir in 2019 (Table 2). A postseason foot survey of the entire Buskin River was conducted to count fish (flooding occurred after the weir was removed) and this added an estimated 500 fish to the escapement count. The inriver run (lower weir count plus postseason survey estimate) of coho salmon in the Buskin River for 2019 was 5,537 fish, of which approximately $9 \%$ was estimated (Tables 1 and 2, Appendix A2).
In 2019, anglers fishing the Buskin River drainage caught an estimated 1,439 coho salmon and harvested 934 coho salmon, expending 11,508 angler-days of effort (Table 1). The reported coho salmon subsistence harvest was 340 fish, and the commercial harvest of Buskin River coho salmon was zero. The estimated spawning escapement was 5,350 (SE 68). The estimated total run was 6,624 (SE 271 coho salmon.

## Exploitation Rate

The estimated subsistence exploitation rate in 2019 was $5.1 \%$ (SE $0.2 \%$ ), whereas the sport exploitation rate was $14.1 \%$ (SE $4.5 \%$ ); the commercial fisheries exploitation rate was zero, making the total estimated exploitation rate $19.2 \%$ (SE 4.4\%; Table 3).

## Age, Sex, and Length

A total of 91 coho salmon were sampled for sex and length from the inriver run, of which age was determined for 88 samples (Table 5). The run accounted for an estimated $52.3 \%$ age- 2.1 fish and $30.7 \%$ age-1.1 fish. Males represented $51.6 \%$ of the run, giving a male-to-female ratio of 1.1:1. There was a significant difference in length between males and females ( $Z=2.48, P=0.01$ ).
Comparison between the distribution of the age-sex-length sampling to the lower weir counts in 2019 shows the ASL sample is fairly well distributed with respect to the weir counts (Figure 5).

## DISCUSSION

## Total Run

There are several sources of bias and unaccounted variability in the estimates of total run for both 2018 and 2019. One source of bias lies in unreturned subsistence permits. This bias is not thought to be large because the subsistence harvest typically represents only about $10 \%$ of the total run and the average rate of permit return in 2018 and 2019 was $87.9 \%$.
A second source of unquantifiable bias comes from the assumption that $20 \%$ of the sport harvest occurs upstream of the lower weir. This number originated from a creel survey in 1986 by Murray (1987) and probably fluctuates annually, with a possible (unknown) trend over time.

A third and probably the most important source of bias and variability is the estimation of lower weir counts for periods when the weir was inoperable due to floods (2018) and the estimation via a postseason foot survey of the fish that entered the river after the weir was removed (2018 and 2019). It is important to note that the reported standard errors of the total run, escapement, age-sex composition estimates, exploitation rates, and brood year returns are therefore biased low because they only account for variance in the estimates of sport harvest and age composition and not in the estimation of counts during flood periods and postseason counts.

An updated brood table for Buskin River coho salmon, incorporating returns from brood years 2012 through 2015, was also developed using all available Buskin River weir data. The latest run data will be used in the next evaluation of the escapement goal in coordination with the Kodiak Board of Fish cycle.

## Age, SEX, AND LENGTH

For both 2018 and 2019, age 2.1 fish were dominant, with age 1.1 fish representing most of the remainder. Age 3.1 was a substantial contributor (13.6\%) in 2019, however. Males were smaller than females, although not significantly so for 2018. As noted above, standard errors of the agesex composition of the total run are biased low due to the unaccounted variability in the estimation of the inriver run and therefore the total run for each year. Sampling did not occur throughout the migration for 2018 and focused on the middle of the run, whereas the bulk of the weir counts occurred in the tail ends of the run. Sampling was dictated by fish availability and could not occur on days when the weir was inoperable due to flooding; therefore, age class estimates may not be representative of the total run for 2018. Sampling in 2019 generally followed inriver run timing.

## Exploitation Rate

The total exploitation rate of Buskin River coho salmon ranged from $19.2 \%$ in 2019 to $41.6 \%$ in 2018. Exploitation in the sport fishery ranged from 1.5 to 2.7 times higher than that of the subsistence fishery (Table 3).

## ACKNOWLEDGMENTS

The authors thank ADF\&G seasonal technicians Graham Briley, Mary Evans, Iris Fletcher, Shawna Lechner, Aeson Sweat, Corina Torgeson, and Michaela Zurflueh for their contributions in the field. Kodiak Area Management Biologist Tyler Polum and Fisheries Biologist Michelle Stratton contributed to this project in every capacity as well. ADF\&G biometrician David Evans (retired at time of publication) helped with statistical aspects of the study. This investigation was partially financed by the Federal Aid in Sport Fish Restoration Act (16 U.S.C. 777-777K) under Project F-10-34 Job S-2-32.

Note: Shaded values are inseason estimates. NA means not applicable. An en dash indicates dates when counts or estimates were not made for the lower weir.
a Count for 12 August comes from the lake weir.
N b Daily total (weir count plus estimate) followed by inseason estimate in parentheses.
c Source: Schmidt et al. (2014) for 2010 estimates, Polum and Evans (2017) for 2011-2013 estimates, Stratton and Evans (2020) for 2014-2017 estimates. Inseason estimates were made due to high water events.
d Source: Schmidt et al. (2014) for 2010 estimates, Polum and Evans (2017) for 2011-2013 estimates, Stratton and Evans (2020) for 2014-2017 estimates. Postseason estimates were made after the weir was pulled.
e Season total is cumulative weir count plus postseason estimate.

Appendix A2.-Daily counts, cumulative counts, and percent of total counts of coho salmon through the Buskin River lower weir; inseason and postseason estimates included, 2015-2019.

Note: Shaded values are inseason estimates. NA means not applicable. An en dash indicates dates when counts or estimates were not made for the lower weir.
${ }^{\text {a }}$ In 2018, estimates were based on extrapolated daily counts and a postseason foot survey (Table 2).
b In 2019, estimates were based on a postseason foot survey (Table 2).
c Count for August 13 comes from a preseason raft survey.
d Daily total (weir count plus estimate) followed by inseason estimate in parentheses.
e Source: Stratton and Evans (2020) for 2014-2017 estimates. Inseason estimates were made due to high water events.
f Source: Stratton and Evans (2020) for 2014-2017 estimates. Postseason estimates for 2018 and 2019 come from foot surveys described in this report.
g Season total is cumulative weir count plus postseason estimate.
