1. Genetic sampling for chum salmon from the South Unimak and Shumagin Islands June fisheries, 1993-1996 and post-June fisheries, 1996-1997. Sampling was conducted at commercial catch processing facilities and by test fishing. Genetic analysis from commercial catch of the June fisheries only are presented in this report.33
2. Daily catch and number of samples analyzed for genetic analysis of South Unimak and Shumagin Islands June fisheries, 1993-1996. Number of fish anlayzed is proportional to the daily catch.34

3a. Chum salmon populations used to construct baseline for analysis of the South Unimak and Shumagin Islands June fisheries and sources of data. Data sources are designated as follows: 1) Seeb and Crane, submitted, 2) this report, 3) Sarafin (1995b), 4) USFWS (unpublished), 5) Wilmot et al. (1994)
6) Kondzela et al. (1994), 7) Phelps et al. (1994), 8) Winans et al. (1994), 9) Wilmot et al. (1994)

3b. Comparison of 1995 baseline and the baseline used in this study to determine the origin of fish sampled from the South Unimak fishery 1993-1996 and the Shumagin Islands fishery 1994-1996 in June.42
4. Mean estimated contribution for 100 simulations where each region comprises $100 \%$ of the mixture ( $\mathrm{N}=400$ ). Shaded cells are correct allocations and should equal 1.00. Standard errors are given immediately beneath a mean contribution estimate.43
5. Estimated contributions of Pacific Rim salmon to a.) the South Unimak June fishery 1993-1996, b.) the Shumagin Islands June fishery, 1994-1996, and c.) combined South Unimak and Shumagin Islands June fisheries. Confidence intervals were estimated by 500 bootstrap resamples of the mixture and baseline.44
6. a. Haplotype frequencies of AseI polymorphisms from the ND5/ND6 region of chum salmon mtDNA. Results from chum salmon sampled in the June South Unimak and Shumagin Islands fisheries, 1994-1996. b. Estimates of the Japanese component of the June South Unimak and Shumagin Islands fisheries, Period 2, 1994-1996 are given; allozyme results are from Table 5.

## LIST OF FIGURES

> Figure Page

1. Approximate sampling locations of pooled population groups of chum salmon in the baseline used in the analysis of the South Unimak and Shumagin Islands June fisheries, 1993-1996. Numbers correspond to location names in Table 3a. Reporting regions are delineated47
2. Map of the South Alaska Peninsula fishery management districts................................. 48
3. Multidimensional scaling analysis of chum salmon population groupings around the Pacific Rim. Numbers of the population groupings correspond to those in Table 3a. Cavalli-Sforza and Edwards chord distance (Cavalli-Sforza and Edwards1967) was used49
4. Annual contribution estimates for South Unimak June fishery, 1993-1996 and Shumagin Islands June fishery, 1994-1996. Averages were computed from individual period estimates weighted by catch size for that period. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/SOUTHERN RUSSIA, and NORTHERN RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON50
5. Contribution estimates by period for the South Unimak June fishery, 1993-1996. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/ SOUTHERN RUSSIA, and NORTHERN RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/ WASHINGTON51
6. Contribution estimates by period for the Shumagin Islands June fishery, 1994-1996. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/ SOUTHERN RUSSIA, and NORTHERN RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/ WASHINGTON

## EXECUTIVE SUMMARY

- Genetic stock identification was used to estimate the origin of chum salmon Oncorhynchus keta harvested in the South Unimak and Shumagin Islands fisheries in June.
- Over 14,000 chum salmon were sampled from fish caught during the June commercial fishery at South Unimak Island from 1993-1996 and the Shumagin Islands from 1994-1996.
- The 1993 South Unimak fishery was stratified into 2 periods, June 13-20 and June 22-29 and the South Unimak and Shumagin Islands 1994-1996 fisheries were stratified into three periods, the opening of the fishery - June 20 (Period 1), June 21-25 (Period 2), and June 2630 (Period 3). For each fishery, 400 fish were randomly subsampled from the total number of fish collected in each period, proportional to the daily catch. Genetic variation was assayed at 20 allozyme loci on the subsampled fish and used to estimate stock composition for the South Unimak and Shumagin Islands fisheries.
- The allozyme baseline compiled by Seeb et al. (1995) was expanded with allele frequency data for 83 populations from Western Alaska, Canada, China, and Russia. The updated baseline comprised 248 collections of chum salmon that were condensed into 109 pooled population groupings. A multidimensional scaling analysis and simulation study on the pooled population groupings suggested 10 reporting regions could be identified in mixtures: 1) JAPAN; 2) CHINA/SOUTHERN RUSSIA; 3) NORTHERN RUSSIA; 4) NORTHWEST ALASKA SUMMER; 5) FALL YUKON; 6) ALASKA PENINSULA/KODIAK; 7) SUSITNA RIVER; 8) PRINCE WILLIAM SOUND; 9) SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA; and 10) SOUTHERN BRITISH COLUMBIA/WASHINGTON (Figure 1).
- Stock contributions for each period of the June South Unimak fishery samples, 1993-1996, and June Shumagin Islands fishery samples, 1994-1996, were estimated via maximum likelihood. Ninety percent confidence intervals were computed for all regional estimates from 500 bootstrap resamples of the baseline and mixture. Annual contribution estimates were calculated as a weighted average for each year with the contribution estimates for a period weighted by the total catch for that period. Ninety percent confidence intervals were also calculated for the annual contribution estimates.
- Annual contribution estimates indicated that NORTHWEST ALASKA SUMMER was the largest individual contributor to both the South Unimak and Shumagin Islands June fisheries. Annual contributions ranged from 0.40 to 0.65 in the South Unimak fishery, from 0.36 to 0.52 in the Shumagin Islands fishery, and from 0.38 to 0.60 in the two fisheries combined. In two of the three years where both fisheries were sampled, the South Unimak fishery had a larger proportion of NORTHWEST ALASKA SUMMER fish than the Shumagin Islands fishery. Asia was the second largest contributor to these fisheries, followed by ALASKA

PENINSULA/KODIAK. Estimates for CHINA/SOUTHERN RUSSIA, FALL YUKON, PRINCE WILLIAM SOUND, and SUSITNA RIVER indicated these reporting groups were a small component or were absent in the fisheries sampled.

- Variation in reporting region contribution was evident within years in each fishery. Reporting regions that made especially strong or small contributions in a year did so in both South Unimak and Shumagin Islands fisheries.
- The Japanese component of the Period 2 stratum of the South Unimak and Shumagin Islands fisheries, 1994-1996, was verified with an independent genetic marker. Period 2 fish were
assayed for variation at the ND5/ND6 region of mitochondrial DNA (mtDNA); the relative contribution of JAPAN was estimated using maximum likelihood and the mtDNA baseline of Park et al. (1993). Estimates based on allozymes and mtDNA for JAPAN were concordant and, in five out of six cases, statistically indistinguishable.

## INTRODUCTION

Migratory and local chum salmon Oncorhynchus keta are harvested in the South Unimak and Shumagin Islands salmon fisheries in June. The catch of chum salmon in these fisheries may contribute to conservation and allocation problems in certain areas. For example, spawning escapements in certain streams in Norton Sound, the Kuskokwim River, and the Yukon River have sometimes been below historic levels in recent years (Eggers 1995). Stock composition of chum salmon harvested in the South Unimak and Shumagin Islands June fisheries has been estimated using traditional tagging methods (Eggers et al. 1991), and more recently, using genetic stock identification (GSI) (Seeb et al. 1995) in order to begin addressing the potential impact of these fisheries on chum salmon stocks in western Alaska.

Seeb et al. (1995) estimated the origin of 2,000 chum salmon individuals caught in the South Unimak fishery in 1993 and 1994 using GSI. Genetic stock identification is the use of the genetic stock structure of a species (baseline) to estimate the contribution of each stock to a mixture given the frequency of genetic marks in the mixture, and has become an important part of many salmonid management programs (chum salmon: Shaklee and Phelps 1990, Phelps et al. 1994; chinook salmon: Utter et al. 1987, Marshall et al. 1991, Miller et al. 1993; pink salmon: White and Shaklee 1991, White 1996; and sockeye salmon: Wood et al. 1989, Seeb et al. 1996).

Protein variation detected by allozyme electrophoresis has been used to delineate the stock structure of chum salmon around the Pacific Rim (Japan: Winans et al. 1994; Russia: Winans et al. 1994, Wilmot et al. 1994; northwestern and southcentral Alaska: Seeb and Crane, submitted; Southeast Alaska: Kondzela et al. 1994; British Columbia: Kondzela et al. 1994, Phelps et al. 1994; and Washington: Phelps et al. 1994). Altogether, these studies form one of the most
comprehensive genetic database for any fish species in terms of the number of populations and genetic markers examined. From these data, Seeb et al. (1995) constructed a genetic baseline of 69 stock groupings from around the Pacific Rim, and used them to estimate stock contribution to eight reporting regions: 1) Japan; 2) Russia; 3) Northwest Alaska Summer; 4) Fall Yukon; 5) Alaska Peninsula/Kodiak Island; 6) Southeast Alaska/Prince William Sound; 7) British Columbia; and 8) Washington. Further, the Japanese component was verified for a portion of the 1994 fishery with an alternative genetic mark using a mitochondrial DNA (mtDNA) marker and the mtDNA baseline of Park et al. (1993).

In this report, we expanded upon the pilot study of Seeb et al. (1995). Fishery sampling included the Shumagin Islands fishery (1994-1996) as well as the South Unimak fishery, 19951996. The Pacific Rim baseline was enlarged from 69 to 109 stock groupings including new data from populations from Alaska, Canada, and Asia. Fishery estimates were provided for 10 reporting regions: 1) JAPAN, 2) CHINA/SOUTH RUSSIA, 3) NORTHERN RUSSIA, 4) NORTHWEST ALASKA SUMMER, 5) FALL YUKON, 6) ALASKA PENINSULA/KODIAK, 7) SUSITNA RIVER, 8) PRINCE WILLIAM SOUND, 9) SOUTHEAST

## ALASKA/NORTHERN BRITISH COLUMBIA, 10) SOUTHERN BRITISH

COLUMBIA/WASHINGTON. NORTHWEST ALASKA SUMMER was the largest component of the South Unimak and Shumagin Islands June fisheries in every year sampled and was a larger component of the South Unimak fishery than the Shumagin Islands fishery in two of the three years sampled. Variability in reporting region estimates occurred both within and among years at both locations. Estimates obtained for the Japanese component for a portion of both fisheries were concordant using two different databases, allozymes and mitochondrial DNA.

## MATERIALS AND METHODS

## Sample Collection

## Baseline

Chum salmon were sampled from spawning populations from southcentral and northwestern Alaska to augment those surveyed in Seeb et al. (1995). Emphasis was placed on areas thought to be underrepresented in the previous baseline, including Norton Sound, Koyukuk River, Kuskokwim River, Yukon River, Alaska Peninsula, and Susitna River. Target sample size for baseline collections was 100 fish to maximize the precision of allele frequency estimates (Allendorf and Phelps 1981). Samples of muscle, liver, eye, and heart were dissected from freshly killed fish, placed in labeled cryovials and frozen on dry ice or liquid nitrogen until transferred to $-80^{\circ} \mathrm{C}$ storage.

## Fishery

The South Unimak June fishery occurs in the Unimak and Southwestern Districts and the Shumagin Islands June fishery occurs in the Shumagin Islands Section of the Southeastern District (Figure 2). Sampling of chum salmon harvested in these fisheries was conducted at Peter Pan Seafoods, King Cove (1993-1996), and Trident Seafoods, Sand Point (1994-1996). Chum salmon were sampled from tender deliveries; tender operators were interviewed to determine the origin of the catch and, to the extent possible, fish were sampled proportionally to the size of the catches made in different fishing areas (Sarafin et al. 1995; Sarafin 1995a). Muscle, liver, and heart tissues were subsampled from each fish, placed in labeled cryovials, and frozen at $-20^{\circ} \mathrm{C}$. Tissue samples were shipped to the Anchorage Genetics Laboratory within one week of collection on dry ice, and stored at $-80^{\circ} \mathrm{C}$.

The South Unimak and Shumagin Islands June commercial fisheries were stratified into three time periods for the 1994-1996 fishery estimates: the opening of the commercial fishery to June 20; June 21 to June 25; and June 26 to June 30 (Seeb et al. 1995). This stratification allowed comparison to stock composition estimates from previous studies (tagging, Eggers et al. 1991; GSI, Seeb et al. 1995) and also to compare estimates from each period across years. For the 1993 South Unimak fishery, the commercial fishery was stratified into two time periods: the opening of the commercial fishery to June 20 and June 21 to June 30 (Seeb et al. 1995). Stock composition estimates were made for the South Unimak and the Shumagin Islands fisheries for each period by randomly subsampling 400 fish proportional to the daily catch rate in each period at each location.

Chum salmon were also sampled from June South Unimak and Shumagin Islands testfisheries 1994-1996, July Shumagin Islands testfisheries 1996-1997, and the post-June South Peninsula commercial fishery 1996-1997. Results from the analysis of these samples will be presented in subsequent reports.

## Laboratory Methods

## Allozymes

Baseline populations and fishery subsamples were assayed for genetic variation at the following loci: $s A A T-1,2^{*} ; m A A T-1^{*} ; m A H-3^{*} ; A L A T^{*} ; E S T D * ; G 3 P D H-2^{*} ;$ GPI-A*; GPIB1,2*; mIDHP-1*; sIDHP-2*; LDH-A1*; LDH-B2*; sMDH-A1*; sMDH-B1,2*; mMEP-2*; $s M E P-1^{*} ; M P I^{*} ; P E P A * ; P E P B-1^{*}$; and $P G D H^{*}$ using the laboratory protocols of Seeb et al. (1995). We used the genetic nomenclature of the American Fisheries Society (Shaklee et al. 1990).

## Mitochondrial DNA

Mitochondrial DNA (mtDNA) was extracted from two baseline populations from Asia (Naiba River, Avakumovka River; obtained from National Marine Fisheries Service, Auke Bay Laboratory) and from the 400 individuals analyzed for the Period 2 subsamples (June 21 - June 25, see above) for the South Unimak fishery and Shumagin Islands fishery 1994-1996. DNA was isolated from heart tissue in 96-well microtiter plates using a high salt precipitation method (modified from Miller et al. 1988 and Sambrook et al. 1989; Gentra Systems, Minneapolis, MN). The primers described in Cronin et al. (1993) were used to amplify the ND5/ND6 region of the mtDNA genome via the polymerase chain reaction (PCR). PCR reactions were conducted in a total volume of $25 \mu \mathrm{l}$ with a final concentration of $2.5 \mathrm{mM} \mathrm{MgCl}_{2}, 1.0 \mathrm{mM}$ each dNTP, $5 \%$ DMSO, and $0.025 \mathrm{U} / \mu \mathrm{l}$ Amplitaq DNA polymerase (Perkin Elmer). Cycling conditions included an initial denaturation at $95^{\circ} \mathrm{C}$ for 2.5 minutes, followed by 25 cycles at $95^{\circ} \mathrm{C}$ for 1 min 40 sec , $58^{\circ} \mathrm{C}$ for 1 min 45 sec , and $72^{\circ} \mathrm{C}$ for 2 min 20 sec . A final extension was performed at $72^{\circ} \mathrm{C}$ for 5 min. Polymorphisms were detected with the restriction enzyme AseI. Sizes of restriction fragments were estimated by comparison with a 100bp DNA Ladder (Gibco-BRL) and lamda DNA digested with BSTE II. Haplotype nomenclature follows that of Park et al. (1993).

## Statistical Analysis of Fishery Samples

## Allozymes

We used the Pacific Rim baseline described in Seeb et al. (1995), with some modifications. One Russian population, Korf Bay, was deleted because of small sample size (Wood et al. 1987). New population data were incorporated into the baseline following data standardization procedures in Seeb et al. (1995) (Appendix 1, Seeb et al. 1997). Loci used in the baseline
analyses were those assayed in the baseline and fishery samples (see above).
Collections sampled at the same location in multiple years were pooled (Shaklee and Phelps 1990). Seeb et al. (1995) further reduced the number of populations in the baseline to improve model efficiency by comparing allele frequencies among populations using a G-Statistic (Sokal and Rohlf 1995). Populations were pooled if no heterogeneity was detected ( $\alpha<0.01$ ). In order to incorporate additional data from western Alaska and Canada into the baseline, heterogeneity among populations from these regions was re-evaluated using a hierarchical Gstatistic analysis (modified from Smouse and Ward 1978). Populations were pooled if no significant differences occurred (Milliken and Johnson 1984, $\alpha=0.05$ ). The heterogeneity analysis was performed using S-Plus version 3.3 analytical software (Mathsoft, Inc., Seattle, WA.).

Potential reporting regions for the maximum likelihood estimates (MLEs) were selected from a multidimensional scaling analysis of Cavalli-Sforza and Edwards chord distances (CavalliSforza and Edwards 1967) calculated among the stock groupings. Distances were calculated using S-Plus; the multidimensional scaling analysis was done in NTSYS version 1.80 (Exeter Software, Setauket, NY). Reporting regions were optimized based on simulations where baseline and mixture genotypes were randomly generated from the baseline allele frequencies using Hardy-Weinberg expectations. Each simulated mixture (N=400) was composed $100 \%$ of the reporting region under study, with each stock group in the reporting region contributing equally to the mixture. Average estimates of mixture proportions were derived from 100 simulations. Reporting regions were enlarged until approximately $90 \%$ of the mixture on average was allocated to the correct region. Simulations were performed using the Statistical Package for Analyzing Mixtures (SPAM95, ADF\&G 1997).

Stock contributions for each period of the South Unimak fishery samples, 1993-1996, and Shumagin Islands fishery samples, 1994-1996, were estimated via maximum likelihood (Pella and Milner 1987; Masuda et al. 1991). A conjugate gradient searching algorithm using a square root transformation was employed (Pella et al. 1996). This algorithm provides good performance with large baselines and small stock differences (Pella et al. 1996). The twenty loci assayed in the fishery samples were used in the estimation procedures, with one exception. One locus, $A L A T^{*}$, was deleted in the analysis of the Shumagin Islands 1996 fishery due to poor resolution in these samples. Genotypes were removed from the mixture in the estimation procedure if their probability of occurring was $P<1 \times 10^{-6}$. For these cases, the mixture estimates have an unknown group containing the percent of the mixture that was removed. Further, we deleted any individual missing data at four or more loci. Individual population or stock estimates were first calculated, then summed into regional groupings (allocate-sum procedure, Wood et al. 1987).

Ninety percent confidence intervals for all regional contribution estimates were computed from 500 bootstrap resamples of the baseline and mixture genotypes. For each resample, contribution estimates were generated for all populations and summed to the regional level. The 500 estimates for a region were then sorted from lowest to highest with the 26th and 475th values in the sequence taken respectively as the lower and upper bounds of the $90 \%$ confidence interval for that region.

Annual contribution estimates were calculated as a weighted average for each year with the contribution estimates for a period weighted by the total catch for that period. Confidence intervals for the annual contribution estimates were computed from 500 bootstrap resamples of the baseline and mixture genotypes for each year and period. For each resample, contribution
estimates were generated for each period within a year and a weighted annual average was calculated as described above. The 500 estimates for each region within a year were then sorted from lowest to highest with the 26th and 475th values in the sequence taken respectively as the lower and upper bounds of the $90 \%$ confidence interval for the annual contribution for that region. Annual contribution estimates were also calculated for the combined South Unimak and Shumagin Islands June fishery as a weighted average for each year with the contribution estimates for a fishery weighted by the total catch for that year. Mitochondrial DNA

Mitochondrial DNA were used to estimate the Japanese and non-Japanese component to the Period 2 stratum of the 1994, 1995, and 1996 South Unimak and Shumagin Islands fishery. Baseline mtDNA data were from Park et al. (1993) and from new data available from Naiba River (Sakhalin Island) and Avakumovka River (Primorye Region, Russia) (ADF\&G, unpublished, available upon request). Stock contributions were estimated, and $90 \%$ bootstrap confidence intervals were computed in the same manner as the allozyme data.

## RESULTS

## Fishery Sampling

Approximately 29,000 chum salmon were sampled from test and commercial fisheries during June and July off the South Alaska Peninsula from 1993 to 1997 (Table 1). Almost 15,000 chum salmon were sampled from the South Unimak and Shumagin Islands June fisheries; this report is based on the analysis of these samples. Approximately half of the June commercial catch samples were assayed for genetic variation (Table 1); we intentionally oversampled to ensure that each fishery sampling was representative (Shaklee and Phelps 1990). For each fishery, samples for analysis were randomly selected from the total number collected within each time strata, weighted proportionally to the daily catch (Table 2 ).

## Statistical Analysis of Fishery Samples

## Pacific Rim Baseline

The baseline data set for chum salmon was composed of 248 collections (Table 3a). Allele frequency data from 83 collections were added to the baseline used by Seeb et al. (1995), including 68 from western Alaska (this report), 10 from Canada (this report; Wilmot et al. 1994; USFWS unpublished), and five from the Amur River, the Primorye region of Russia, and Sakhalin Island in Asia (Wilmot et al. 1995). The final baseline used in this fishery analysis comprised 109 pooled populations groupings (Table 3a, 3b; Figure 1) (see below).

Populations from western Alaska and Canada were pooled into enlarged stock groupings based on the results of a hierarchical G-Statistic analysis (Appendix 2, Seeb et al. 1997). The 101 collections from summer- and fall-run populations in northwestern Alaska were pooled into 23 stock groupings. No heterogeneity of allele frequencies was detected within the following
drainages or regions: lower Noatak River; Norton Sound; Andreafsky River; Anvik River; earlyrun Koyukuk River; late-run Koyukuk River; early-run Tanana River; upper fall-run Tanana River; Porcupine River; Yukon River-Canadian Mainstem; White River; early-run Kuskokwim River; late-run Kuskokwim River; northern Bristol Bay; Kvichak Bay; Egegik/Ugashik Bay; Meshik/Cinder Rivers; or the Susitna River. Allele frequency heterogeneity was detected within the Noatak River drainage and between the Noatak and Kobuk Rivers. Differences in allele frequencies occurred among rivers draining into the Yukon River; in addition, temporal differences in allele frequencies existed among early- and late-run populations in the Koyukuk and Tanana Rivers. Temporal differences in allele frequencies also occurred between early- and laterun collections in the Kuskokwim River. Heterogeneity was detected among rivers draining into Bristol Bay.

Comparatively more heterogeneity occurred among populations from the Alaska Peninsula and Kodiak Island. Of the 40 populations sampled in this region, only Sturgeon River (Kodiak Island) and Kitoi Hatchery were pooled (the brood source for Kitoi Hatchery is the Sturgeon River). No allele frequency differences were detected among populations sampled in western Prince William Sound, but heterogeneity did occur among populations in eastern Prince William Sound.

Pooled population groupings in the Pacific Rim baseline (see Appendix 3, Seeb et al. 1997 for baseline allele frequencies) were plotted using a multidimensional scaling analysis (Figure 3). Five non-overlapping groups were apparent: fall-run Yukon River, summer-run populations from northwestern Alaska, Susitna River, northern Russia, and populations from Washington and southern British Columbia. Overlap was observed between populations from Prince William

Sound, the Alaska Peninsula, Kodiak Island, southeastern Alaska, and northern British Columbia. Populations from Japan were well separated from populations from North America. However, some overlap was apparent between Japan and the very divergent populations from the Amur River, Sakhalin Island, and southern Russia.

Ten potential reporting regions were selected from the multidimensional scaling analysis:

1) JAPAN, 2) CHINA/SOUTHERN RUSSIA, 3) NORTHERN RUSSIA, 4) NORTHWEST ALASKA SUMMER, 5) FALL YUKON, 6) ALASKA PENINSULA/KODIAK, 7) SUSITNA RIVER, 8) PRINCE WILLIAM SOUND, 9) SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and 10) SOUTHERN BRITISH COLUMBIA/WASHINGTON. The ability of these reporting regions to be correctly identified in mixtures was evaluated using simulations where each simulated mixture was composed of $100 \%$ of a reporting region. Within the region, the individual populations were constrained to contribute equally to the sample (no allowances were made for differential abundances). Mean estimates from 100 simulations indicated that all reporting regions showed at least $90 \%$ accuracy with the exception SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA where accuracy dropped to 86\% (Table 4). Stock contributions of these 10 reporting regions were estimated for the South Unimak and Shumagin Islands fisheries (see Appendix 4, Seeb et al. 1997 for fishery allele frequencies).

## Fishery Estimates

## South Unimak Fishery

The annual estimates for the South Unimak fishery indicated that the largest contributor was NORTHWEST ALASKA SUMMER, followed by the combined Asian reporting groups (Table 5, Figure 4). The NORTHWEST ALASKA SUMMER component of the chum salmon
harvest was the largest for each year sampled, ranging from an annual low in 1996 (0.40) to a high in 1995 (0.65). The other major individual contributors were JAPAN, NORTHERN RUSSIA, and ALASKA PENINSULA/KODIAK. JAPAN was the second largest contributor in 1993 and 1995, and its contribution was fairly consistent from year to year, ranging from 0.12 to 0.16. NORTHERN RUSSIA was the second largest contributor in 1994 (0.14), and ALASKA PENINSULA/KODIAK was the second largest contributor in 1996 (0.17). However, the contributions of these reporting groups were not consistent from year to year, varying from 0.06 to 0.14 for NORTHERN RUSSIA and 0.03 to 0.17 for ALASKA PENINSULA/KODIAK. Smaller components ( 0.00 to 0.09 ) were observed for CHINA/SOUTHERN RUSSIA, FALL YUKON, SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON.

In 1993, reporting region contributions were nearly equivalent between the two time strata, with the exception of ALASKA PENINSULA/KODIAK (Table 5, Figure 5). However, for the other years, variation in reporting region contribution is evident within years. For example, the NORTHWEST ALASKA SUMMER component ranged from 0.48 to 0.71 in 1994; ranged from 0.58 to 0.76 in 1995; and ranged from 0.33 to 0.44 in 1996. Within-year variation is also evident for the other reporting regions with large contributions. In general, if the contribution of the NORTHWEST ALASKA SUMMER increased over time, the proportion of Asia and, to a lesser extent, ALASKA PENINSULA/KODIAK, decreased (Figure 5).

## Shumagin Islands Fishery

NORTHWEST ALASKA SUMMER was also the largest component of the Shumagin

Islands fishery, followed by the combined Asian reporting groups (Table 5, Figure 4). Annual estimates for NORTHWEST ALASKA SUMMER ranged from 0.36 in 1996 to 0.52 in 1995. Asian reporting groups were the second largest. The JAPAN component ranged from 0.16 in 1994 to 0.24 in 1996, while the NORTHERN RUSSIA component ranged from 0.05 in 1995 to 0.17 in 1994. ALASKA PENINSULA/KODIAK ranged from 0.08 in 1994 and 1995 to 0.19 in 1996. Smaller components ( 0.00 to 0.10 ) were observed for CHINA/SOUTHERN RUSSIA, FALL YUKON, SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON.

Variation in the contribution of reporting regions is evident within years in the Shumagin Islands fishery as well and was most notable in 1995. The contribution of NORTHWEST ALASKA SUMMER decreased from 0.69 in Period 1 to 0.15 in Period 3. Conversely, the JAPAN contribution increased from 0.11 in Period 1 to 0.41 in Period 3; the ALASKA PENINSULA/KODIAK contribution also increased from 0.03 in Period 1 to 0.21 in Period 3. Similar to the South Unimak fishery, changes in the NORTHWEST ALASKA SUMMER component over time were met with a corresponding and opposite change in the Asian and ALASKA PENINSULA/KODIAK component (Figure 6).

## Fishery Comparison

NORTHWEST ALASKA SUMMER was the largest contributor to both fisheries (Figure 4). However, in two of the three years in which both locations were sampled, the NORTHWEST ALASKA SUMMER component was significantly larger in the South Unimak fishery than the Shumagin Islands fishery. Reporting regions that make especially large or small contributions in a
year seem to do so consistently across fisheries. For example, in 1995, the NORTHWEST ALASKA SUMMER component was the highest over all years sampled in both the South Unimak and Shumagin Islands fishery. Similarly, the largest contribution by NORTHERN RUSSIA was made to both fisheries in 1994, and the largest contribution by ALASKA PENINSULA/KODIAK was made to both fisheries in 1996, while the smallest contribution by NORTHWEST ALASKA SUMMER was made to both fisheries in 1996.

NORTHWEST ALASKA SUMMER was the largest contributor to the combined fishery, with estimates ranging from 0.60 in 1995 to 0.38 in 1996 (Table 5). The contribution of JAPAN and ALASKA/PENINSULA KODIAK to the combined fishery increased from 0.13 in 1994 to 0.21 in 1996 and 0.08 in 1994 to 0.18 in 1996, respectively. The contribution of NORTHERN RUSSIA decreased from 0.15 in 1994 to 0.08 in 1996. The contributions of the remaining reporting groups to the combined fishery were less than 0.09 in every year sampled.

## MtDNA Analysis

Mitochondrial DNA variation was analyzed in the South Unimak and Shumagin Islands fisheries, Period 2 stratum 1994-1996 to verify the estimate of the Japanese component given by the allozyme results. Frequencies for the B haplotype, common in Japan (Park et al. 1993), ranged from 0.141 for the South Unimak fishery in 1994 to 0.279 for the Shumagin Islands fishery in 1996 (Table 6). Estimates for JAPAN using mtDNA ranged from 0.11 to 0.25 in the South Unimak fishery and 0.21 to 0.26 in the Shumagin Islands fishery. In every case except South Unimak 1995, the mtDNA estimates for the contribution of JAPAN are within the $90 \%$ confidence intervals for the corresponding allozyme estimates (Table 6). For South Unimak 1995, the mtDNA and allozyme estimates were close, 0.25 and 0.20 respectively.

## DISCUSSION

## Baseline

We expanded upon the baseline used in the Seeb et al. (1995) analysis of the South Unimak fishery by adding populations for previously underrepresented areas. These included fallrun populations from the Canadian portion of the Yukon drainage and the Amur River, Premorye Region of Russia, and Sakhalin Island in Asia. In addition, temporal and geographic coverage was improved for the Alaskan portion of the Yukon River, the Kuskokwim River, the Alaska Peninsula, the Susitna River, and Prince William Sound. Addition of these new populations improves our understanding of population substructure of chum salmon and refines the delineation of reporting groups that can be identified in mixtures.

The addition of new population data from the Alaska Peninsula and Kodiak Island further illustrate the greater heterogeneity observed in this region as compared to northwestern Alaska noted by Seeb and Crane (submitted). The multidimensional scaling analysis of the chum salmon baseline (Figure 3) demonstrated that chum salmon populations from this area are not only very divergent from populations in northwestern Alaska, but are also the most genetically diverse of any area except Sakhalin Island and the Primorye Region of Russia. Seeb and Crane (submitted) attributed this greater observed heterogeneity to multiple recolonization events following the glaciation that occurred in this region during the Pleistocene.

New population data from Alaska further provided additional evidence for the importance of temporal differences in runtiming as an isolating mechanism for chum salmon, already well documented in the Yukon River (Wilmot et al. 1994; Seeb and Crane submitted). Genetic differences were observed between early- and late-run salmon in the Koyukuk River (G-
statistic=96.8, $\mathrm{DF}=42, \mathrm{P}<0.0001$ ) and, more notably, the Kuskokwim River (G-statistic=396.0, $\mathrm{DF}=42, \mathrm{P}<0.0001$ ). The magnitude of difference between early- and late-run Kuskokwim River populations is similar to that between summer- and fall-run chum salmon in the Yukon River.

Wilmot et al. (1995) examined eight populations from China and Russia. They found that chum salmon from Sakhalin Island and the Premorye Region of Russia were intermediate between those from Japan and northern Russia. We used five of these populations in the baseline for the analysis of the South Peninsula fishery. Three of the populations analyzed by Wilmot et al. (1995) had samples sizes of less than 40 individuals; we did not incorporate these because baseline populations with very small sample sizes increase imprecision of stock composition estimates (Wood et al. 1987). Similar to Wilmot et al. (1995), the multidimensional scaling analysis in this study demonstrated that these populations overlap more with Japan than northern Russia. Wilmot et al. (1995) attributed the extreme divergence of the Kalininka River due to a genetic bottleneck; this hatchery population was founded from a small number of individuals, while the Heilong (Amur) River is divergent, similar to upper Yukon River populations, because of extremely long distance migrations.

The addition of new populations refined the reporting regions identified by Seeb et al. (1995). JAPAN and NORTHERN RUSSIA (previously termed 'Russia') were the only reporting groups that remained unchanged. The new populations added from China and southern Russia were unique and formed their own reporting group. In simulations of mixtures entirely composed from CHINA/SOUTHERN RUSSIA, there was essentially no misallocation to NORTHERN RUSSIA and 5\% misallocation to JAPAN.

The NORTHWEST ALASKA SUMMER reporting region included all populations from

Kotzebue Sound to the Meshik River on the north Alaska Peninsula, excluding fall-run Yukon River. However, SUSITNA RIVER was removed from the Northwest Alaska Summer region and made a separate reporting group. More populations were sampled from the Susitna drainage and consistently showed the unusual allele frequencies previously observed by Okazaki (1982) and Seeb and Crane (submitted) in this river. SUSITNA RIVER is the most highly identifiable reporting region. Populations from the Canadian portion of the Yukon River were not represented in the Seeb et al. (1995) baseline. We incorporated populations sampled in Canada from the Porcupine River, Yukon River mainstem, White River, and Teslin River into the FALL YUKON reporting region. Temporal and geographic coverage was expanded for ALASKA PENINSULA/KODIAK.

More populations were sampled in Prince William Sound allowing the formation of a PRINCE WILLIAM SOUND reporting region, separate from Southeast Alaska as in the previous baseline. Though a small amount of overlap was observed with populations from the Alaska Peninsula in the multidimensional scaling analysis, artificial mixtures made from this reporting group allocated with a high degree of accuracy in the simulation study (93\%). Other changes made to the baseline used by Seeb et al. (1995) were combining the genetically similar southern British Columbia and Washington populations into a reporting region and northern British Columbia and southeastern Alaska into a reporting region.

The potential for further refinement of NORTHWEST ALASKA SUMMER into smaller reporting regions is limited; the genetic similarity of chum salmon spawning aggregates in this region is very high. Simulations of the western Alaska portion of the baseline indicated it was clearly not possible to accurately estimate Nushagak River, Togiak River, early-run Kuskokwim

River, and summer-run chum salmon from the lower Yukon River. Correct mean allocations in simulations where reporting groups comprised $100 \%$ of the mixture were less than $75 \%$. Seeb and Crane (submitted) attributed the lack of genetic differences among populations to a historical connection between the Kuskokwim and Nushagak drainages. These rivers likely shared a common outlet to the Bering Sea during the Pleistocene, close to the ancient outlet of the Yukon River. Either there has not been enough time since the geographic separation of these drainages for genetic differences to accrue due to drift or low levels of straying are maintaining allele frequency similarities. However, in other fishery applications smaller reporting regions may be possible.

Accuracy of reporting region estimates is dependent on the sample size of the reporting region in the mixture, as well as the degree of stock separation among reporting regions (Wood et al. 1987). Wood et al. (1987) showed through simulations that a sample size of 40 fish for a reporting region in a mixture, or $10 \%$ of the mixture in this study, is required to accurately estimate that reporting region's contribution. In less complicated mixtures, where not all Pacific Rim stocks are contributing, finer delineation of reporting regions may be possible. For example, in-river Yukon fisheries could potentially be subdivided (JTC 1997).

Additional marker types, such as microsatellites, might provide further discrimination among populations and refinement of the baseline. Microsatellites are nuclear DNA markers that have extremely high mutation rates, exhibit high levels of heterozygosity, and are useful in revealing population substructure when other marker types exhibit low levels of heterozygosity (Bentzen et al. 1996) or when populations are recently derived (Wright and Bentzen 1994). However, in studies where allozyme loci are variable, estimates of populations subdivision using
allozymes are highly concordant with those using microsatellites (chum salmon, Scribner et al. submitted; sockeye salmon, Allendorf et al. submitted; chinook salmon, Scribner et al. 1996; ADF\&G, unpublished data).

## Fishery

Genetic analysis of the South Unimak and Shumagin Islands fishery, 1993-1996, indicated that a large proportion of chum salmon harvested were NORTHWEST ALASKA SUMMER, with the second largest contribution made by the combined Asian stocks. Annual estimate showed that NORTHWEST ALASKA SUMMER was always the largest single contributor and ranged from 0.40 to 0.65 for the South Unimak fishery and 0.36 to 0.52 in the Shumagin Islands fishery. The NORTHWEST ALASKA SUMMER contribution may be larger in the South Unimak than the Shumagin Islands fishery. Though the data are limited, in two of the three years that both fisheries were sampled, the NORTHWEST ALASKA SUMMER proportion was larger in the South Unimak fishery than the Shumagin Islands fishery. Geiger (1997) used the contribution estimates for NORTHWEST ALASKA SUMMER to obtain harvest rates for NORTHWEST ALASKA SUMMER stocks in the South Unimak and Shumagin Islands fisheries.

Reporting group contribution to these fishery samples varies both among and within years. The contribution of NORTHWEST ALASKA SUMMER was significantly smaller in 1996 than in the other years sampled for both fisheries, while the contribution of ALASKA

PENINSULA/KODIAK was twice as large in this year than any other. Reporting region contribution can almost double in size from one time period to another within a year; in 1996, the ALASKA PENINSULA/KODIAK contribution to the South Unimak June fishery increased from 0.14 in Period 2 to 0.31 in Period 3. It is also interesting to note that reporting regions that make
especially strong or weak contributions in a year do so in both the South Unimak and Shumagin Islands fisheries. For example, NORTHERN RUSSIA had its largest component in both the 1994 South Unimak and Shumagin Islands fisheries.

## Estimates for CHINA/SOUTHERN RUSSIA, FALL YUKON, PRINCE WILLIAM

SOUND, and SUSITNA RIVER indicated that these reporting groups were a small component or were absent in the fisheries sampled. Zero was included in the $90 \%$ confidence interval of the annual estimate for CHINA/SOUTHERN RUSSIA in every fishery sample except Shumagin Islands 1994. For FALL YUKON, zero was in the $90 \%$ confidence interval for half of the fishery samples. Zero was included in the $90 \%$ confidence interval for SUSITNA RIVER in every fishery sample except South Unimak 1993, and for PRINCE WILLIAM SOUND in all fishery samples.

Mitochondrial DNA data have not been used routinely in analyses of mixtures of Pacific salmon, though mtDNA markers have been very successful in identifying the origin of striped bass Morone saxatilis (Wirgin et al. 1993) and American shad Alosa sapidissima (Epifanio et al. 1995). Seeb et al. (1995) reviewed the utility of mtDNA variation for verification of the allozyme estimate for JAPAN using the mtDNA baseline of Park et al. (1993). Park et al. (1993) found clinal variation in mtDNA around the Pacific Rim; frequencies for the B haplotype ranged from a mean of 0.8 in Japan, decreasing in frequency in Russia, to near absence in North America. We used mtDNA as an independent check of the Period 2 allozyme estimate for each fishery sampled from 1994 to 1996. In both the South Unimak and Shumagin Islands fisheries samples, the allozyme and mtDNA estimates were concordant, and in five out of six cases, statistically indistinguishable.

Variation in reporting region contribution may be an indication of abundance or temporal
variation in migration timing (Salo 1991). Migration patterns of maturing chum salmon in the north Pacific Ocean were reviewed by Salo (1991). Summer-run chum salmon bound for northwestern Alaska are at their greatest concentrations off the Alaska Peninsula in June, while chum salmon from Japan and eastern Kamchatka and western Bering Sea move from the Gulf of Alaska into the Bering Sea during this month as well (Salo 1991).

The formation of a Pacific Rim baseline for chum salmon has allowed researchers to use GSI techniques to estimate the stock contribution of mixtures of chum salmon in the Bering Sea and North Pacific Ocean. Wilmot et al. $(1995,1996)$ used the baseline of Seeb et al. (1995) and eight additional populations from China and southern Russia to estimate the origin of chum salmon harvested incidentally in the 1994 and 1995 Bering Sea "B" fishery for walleye pollock Theragra chalcogramma. The majority of fish sampled in both years were immature; composition estimates differed substantially for immature and adult chum salmon. Approximately one half of the immatures were Asian in origin while the Northwest Alaska Summer contribution ranged from $23 \%$ to $34 \%$. The majority of the adults were from British Columbia, Washington, or Japan.

Urawa et al. (1997) used the baselines of Seeb et al. (1995) and Wilmot et al. (1995, 1996) to determine the composition of chum salmon sampled in the North Pacific Ocean and Gulf of Alaska in January 1996 and the North Pacific Ocean, Bering Sea, and Gulf of Alaska in late June and early July, 1996. Similar to Wilmot et al. (1995, 1996), the majority of fish sampled were immatures. For the North Pacific Ocean and Bering Sea sampling locations, the majority of fish were Asian in origin for both immatures and adults. However, the stock composition of chum salmon sampled in the Gulf of Alaska indicated that the majority of immatures were from

Northwest Alaska Summer, with large contributions also made by British Columbia and Russia.
British Columbia and Alaska Peninsula/Kodiak made the largest contribution to the adult sample.
These studies based on GSI support the view that Asian chum salmon have more extensive oceanic migrations than North American chum salmon (Salo 1991). However, Ignell et al. (1997) discussed the fact that their study of the incidence of thermally-marked chum salmon in the Bering Sea pollock "B" trawl fishery and recent GSI studies all indicate that southern Gulf of Alaska populations may be present in the Bering Sea in higher numbers than previously thought from tagging studies. They hypothesized that possible changes in stock composition in the Bering Sea may be due to decadal changes in environmental conditions or population density. Studies such as these, and the continued analysis of chum salmon sampled in the South Peninsula postJune fishery and South Peninsula test fisheries will provide a more detailed understanding of chum salmon migration patterns.

## CONCLUSION

We used genetic stock identification techniques and an extensive allozyme baseline of Pacific Rim chum salmon populations to estimate the composition of chum salmon sampled from the June South Unimak Island and Shumagin Islands commercial catch, 1993-1996. NORTHWEST ALASKA SUMMER was the main component of these fisheries and was a larger component of the South Unimak fishery than the Shumagin Islands fishery in two of the three years sampled. Asian populations were the second largest contributor to these fisheries, followed by chum salmon from the ALASKA PENINSUL/KODIAK ISLAND. Estimates for CHINA/SOUTHERN RUSSIA, FALL YUKON, PRINCE WILLIAM SOUND, and SUSITNA RIVER indicated these regions were a small component or were absent in the fisheries sampled. Variation in reporting region contribution was evident within years in each fishery.

## ACKNOWLEDGEMENTS

We are grateful for the help and cooperation of many people in all phases of this study. Judy Berger, Jeannemarie Skalka, Barb Debevec, and Carol Kerkvliet provided laboratory expertise. Baseline samples were collected by Cindy Anderson, Nancy Bauer, Bob Bercelli, Ian Boyce, Bob Chappel, Mark Cox, Randall Davis, Greg Demers, Wayne Donaldson, Larry Dubois, Dan Gray, Rick Gustin, Paul Headlee, Peggy Merritt, Doug Molyneaux, Ted Otis, Ignatti Petruska, Nick Petruska, Pete Probasco, Robin Reich, Gene Sandone, Dave Sarafin, Sam Sharr, Arnie Shaul, Jeannemarie Skalka, Rob Stewart, and Pete Velsko.

Dave Sarafin and Dan Gray directed the fishery sampling and were aided by Sean Palmer, Jason Osborne, Dave Kean, Jeannemarie Skalka, Chris Schlichten, Stephen Oliveira, Adam Reimer, Eric Meader, Roxanne Rohweder, Kristjan Farmen, Mike Anderson, Jeffrey Mellman collected the fishery samples. We appreciate the assistance of Bob Bercelli, Rod Campbell, Jim Cofske, Wayne Donaldson, Jim McCullough, Pete Probasco, Arnie Shaul, and Ivan Vining of the ADF\&G Region IV staff for designing and implementing the fishery sampling. We also thank the staff of Peter Pan Seafoods, King Cove, and Trident Seafoods, Sand Point for allowing us to conduct fishery sampling at their facilities.

## OFFICE OF EQUAL OPPORTUNITY (OEO) STATEMENT

The Alaska Department of Fish and Game conducts all programs and activities free from discrimination on the basis of sex, color, race, religion, national origin, age, marital status, pregnancy, parenthood or disability. For information on alternative formats available for this and other department publications, please contact the department ADA coordinator at (voice) 907-465-4120, (TDD) 1-800-478-3648, or (fax) 907-586-6596. Any person who believes s/he has been discriminated against should write to: ADF\&G, P.O. Box 25526, Juneau, AK 99802-5526; or O.E.O., U.S. Department of Interior, Washington, D.C. 20240.

Figure 5. Contribution estimates by period for the South Unimak June fishery, 1993-1996. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/SOUTHERN RUSSIA, and NORTHERN RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON).

Figure 6. Contribution estimates by period for the Shumagin Islands June fishery, 1994-1996. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/SOUTHERN RUSSIA, and NORTH RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON).

Figure 1. Approximate sampling locations of pooled population groups of chum salmon in the baseline used in the analysis of the South Unimak and Shumagin Islands June fisheries, 1993-1996. Numbers correspond to location names in Table 3a. Reporting regions are delineated.

Figure 4. Annual contribution estimates for South Unimak June fishery, 1993-1996 and Shumagin Islands June fishery, 1994-1996. Averages were computed from individual period estimates weighted by catch size for that period. Reporting groups were enlarged for readability: ASIA (JAPAN, CHINA/SOUTHERN RUSSIA, and NORTHERN RUSSIA), NORTHWEST ALASKA SUMMER, FALL YUKON, ALASKA PENINSULA/KODIAK, and EASTERN GULF OF ALASKA/PACIFIC NORTHWEST (SUSITNA RIVER, PRINCE WILLIAM SOUND, SOUTHEAST ALASKA/NORTHERN BRITISH COLUMBIA, and SOUTHERN BRITISH COLUMBIA/WASHINGTON).

Figure 3. Multidimensional scaling analysis of chum salmon population groupings around the Pacific Rim. Numbers of the population groupings correspond to those in Table 3a. Cavalli-Sforza and Edwards chord distance (Cavalli-Sforza and Edwards 1967) was used.

Table 1. Genetic sampling for chum salmon from the South Unimak and Shumagin Islands June fisheries, 1993-1996 and post-June fisheries, 1996-1997. Sampling was conducted at commercial catch processing facilities and by test fishing. Genetic analysis from commercial catch of the June fisheries only are presented in this report.

|  |  |  |  | Catch <br> Year <br> Geographic Area |
| :---: | ---: | ---: | ---: | ---: |
| June Fishery | Catch | Test | Total |  |
| Subsample |  |  |  |  |

1"Mainland" refers to fish caught in Unimak District, Southwestern District, Southcentral District or Southeastern District-Mainland Section waters

Table 2. Daily catch and number of samples analyzed for genetic analysis of South Unimak and Shumagin Islands June fisheries, 1993-1996. Number of fish analyzed is proportional to the daily catch.

| Year | Period | Date | South Unimak |  |  |  | Shumagin Islands |  |  |  |

Table 6. a. Haplotype frequencies of AseI polymorphisms from the ND5/ND6 region of chum salmon mtDNA. Results from chum salmon sampled in the June South Unimak and Shumagin Islands fisherie: 1994-1996. b. Estimates of the Japanese component of the June South Unimak and Shumagin Islands fisheries, Period 2, 1994-1996 are given; allozyme results are from Table 5.
a.

| Fishery Sampling | Haplotype Counts |  |  |  |  | Frequencies |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

[^0]:    ${ }^{1}$ The Regional Information Report Series was established in 1987 to provide an information access system for all unpublished divisional reports. These reports frequently serve diverse ad hoc informational purposes or archive basic uninterpreted data. To accommodate timely reporting of recently collected information, reports in this series undergo only limited internal review and may contain preliminary data; this information may be subsequently finalized and published in the formal literature. Consequently, these reports should not be cited without approval of the authors or the Commercial Fisheries Management and Development Division.
