Nomination for Waters
Important to Anadromous Fish

AWC Volume (SE) SC SW W AR IN USGS Quad SITKA D4- NW1/4 Sec.3, T.47S., R.64E

Anadromous Water Catalog Number of Waterway 112-50-10120-2045 TRIB

Name of Waterway PAVLOF RIVER drainage USGS name X Local name ___

Addition X Deletion ___ Correction ___ Backup Information ___

For Office Use

Nomination # 95 251	[signature] 12-13-94 — Regional Supervisor, Date
Revision Year:	[signature] 1/5/95
Revision to: Atlas ___ Catalog ___ Both X	[signature] 1/11/95 — Drafted, Date
Revision Code: A-2	

OBSERVATION INFORMATION

Species	Date(s) Observed	Spawning	Rearing	Migration	Anadromous
coho	5/18/94		x (2)		
DV	5/18/94		x (2)		
cutthroat	5/18/94		1- 12" Long.		

IMPORTANT: Provide all supporting documentation that this water body is important for the spawning, rearing or migration of anadromous fish, including: number of fish and life stages observed; sampling methods, sampling duration and area sampled; copies of field notes; etc. Attach a copy of a map showing location of mouth and observed upper extent of each species, as well as any other information such as: specific stream reaches observed as spawning or rearing habitat; locations, types, and heights of any barriers; etc.

Comments: see attached

ALASKA DEPT. OF FISH & GAME
DEC 27 1994
REGION II HABITAT AND RESTORATION DIVISION

Name of Observer (please print) Phil Mooney / Jim Fincher (USFS)

Date: 11/1/94 Signature: [signature]

Address: DEPT. OF FISH & GAME 304 LAKE ST. RM. 103 SITKA, ALASKA 99835-7563

This certifies that in my best professional judgement and belief the above information is evidence that this waterbody should be included in or deleted from the Catalog of Waters Important for Spawning, Rearing or Migration of Anadromous Fishes per AS 16.05.870.

SUBJECT: 1994 Stream Nominations - Supplemental

FROM: Phil Mooney
Habitat Biologist
Sitka

A number of items on the original chart submitted needed clarification and/or additional information. Enclosed you will find an updated chart to be used with the supplemental information below and the original maps. Please remove the original chart from the nomination package and replace it with this version.

While we were surveying streams this year we also gathered information from the Sitka Area Sportfish biologist, Art Schmidt, to help us intrepret some of results. He provided these general comments (paraphrased below):

1. **Roadside ditches containing very small water volume were found to have coho and DV in them throughout the year, although in some cases they did dry up in mid-summer. How important are these ditches for fish habitat?** Roadside ditches that intercept small drainages across a hillside often concentrate small flows and distribute them in different patterns than originally existed. If fish (anadromous and resident) are found in these ditches, they are obviously finding some suitable habitat. If the ditch is intercepting a spring-fed source of water that provides a constant flow (even if the volume is slight), overwintering fish can move into these areas and avoid anchor ice. A spring-fed source may also provide a constant source of water during drought periods and a more temperature regulated environment than surface waters can. For these reasons, spring-fed systems may be keystone components for fish survival. Some ditches may only provide seasonal habitat. They may intercept and transport fall rains and snowmelt through the fall-winter-spring-and early summer periods. The landscape that provides fish habitat is a dynamic system. It constantly changes due to seasonal and climate flucuations. Physical changes to it are also constantly occurring. Fish populations undergo seasonal distributions, as well as do their food base. Trying to second-guess the importance of a ditch here, small stream there, etc. for fish habitat is a hazardous

over-simplification of the system at work and we need to be cautious of dismissing components of a larger system.

2. **Why did we fail to capture fish in a minnow trap placed in the mainstem when hundreds of fish were visible upstream in overflow areas?** Failure to capture fish in a minnow trap placed in the mainstem when upstream many fry and smolts are visible in shallow, overflow or slow-moving tributaries is likely due to seasonal conditions. Spring flows containing snowmelt are generally colder and have more volume than after snowmelt periods. Fish metabolism and food resources are reduced in late fall, winter, and early spring. In early spring under high water conditions, smolts, emerging fry, and resident fish will seek out warmer, slow moving water thereby reducing the amount of energy needed to swim and maintain themselves. High water conditions also typically carry higher loads of sediment. Because overflow areas are shallow and slow moving, these sections of water will be slightly warmer, food resources will likely be more abundant, and bank cover will provide some protection from predation.

3. **Why did we capture cutthroat trout in the upper reaches of a stream system and yet fail to have them represented in captures downstream when no physical barriers exist to their movement?** Cutthroat trout do not compete well with other rearing fish. Capturing cutthroat in the upper reaches of a stream system and not finding them distributed downstream is fairly common. When pressured, cutthroat will retreat into upper tributaries and less preferred habitat. It is believed that this is one of the reasons cutthroat are so susceptible to losses of habitat in the upper stream reaches and finger tributaries. Seasonal changes in rearing fish distributions are common with different habitats preferred under different seasonal and edaphic conditions.

Please use the information below to supplement the nomination sheets and chart. The reference # refers to the reference # column (A) found on the chart.

<u>Reference #</u>

1. Approximately 6 additional CO smolts were seen in a 50' distance downstream from the culvert. Dolly Varden char were also present in the stream. This stream appears to be providing overwintering habitat for salmon and is a short distance (less than 1/4 mile from the Kennel Creek mainstem).

2. Although only 1 coho smolt was netted, more than a half dozen were observed along portions of the ditch. More than 10 DV were also counted in the ditch. The ditch parallels the road for more than 300' and gradually angles towards the mainstem of Kennel Creek, until it is within 80' of the mainstem. Water remained running in this ditch throughout the summer, even through extended dry periods, providing fish habitat.

3. Soak time of the minnow trap was approximately 1 hour. The trap was located in the mainstem and captured no fish. The bulk of the fish were located 100' upstream of the trap site in a shallow overflow area where water temperatures were warmer than the mainstem. The coho fry and DV were active and numerous. Two coho fry were netted for identification purposes and released. DV were observed but not captured.

4. Other fish, both coho fry and DV, were observed during a short walk (50') downstream from the culvert. We briefly looked for fish above the culvert and found none although suitable habitat exists for more than 1/4 mile. The culvert was partially blocked by debris on the uphill side and the lower side is perched >8".

6. The trap soaked for 45 minutes. Two coho fry, 15 DV, and one cutthroat were captured. Many other cohos and DV were seen above and below the trap site. It appeared that this is a very productive stream.

9. No other fish were seen due to snowcover that was still extensive here. Judging from the limited distance of stream we could survey, stream gradient, visible habitat and the two fish caught in a short distance, this stream provides adequate suitable fish habitat for additional fry/smolts. Re-survey at a later date was not accomplished this summer.

11. This stream has excellent fish habitat and appeared to be very productive. Stream flows did not noticeably vary after storm events. It is likely this stream is spring-fed and may provide overwintering habitat for fish.

18. Although we did not capture salmon species in the minnow trap, this stream is a tributary to Bayhead Cr., with pink and coho salmon species in it. The number of cutthroat captured indicates a good fish habitat condition. Without additional work, I can not say for sure that the DV or cutthroat are anadromous. This stream should be documented for cutthroat at this time.

19. Stream was not surveyed extensively due to boat anchoring problems and stormy conditions. Suitable fish habitat and stream gradient is present. FS personnel (Hoonah RD fisheries staff) said they have also seen coho fry in this stream. They list the lower portion of the stream as a Class I system.

21. Due to limited time and poor weather conditions, no attempt was made to capture more fish. Lighting was poor at the time of the survey. Adequate fish habitat does exist and provides rearing habitat for cohos.
