Symbols and Abbreviations

The following symbols and abbreviations, and others approved for the Syst me International d'Unit s (SI), are used without definition in the following reports by the Divisions of Sport Fish and of Commercial Fisheries: Fishery Manuscripts, Fishery Data Series Reports, Fishery Management Reports, and Special Publications. All others, including deviations from definitions listed below, are noted in the text at first mention, as well as in the titles or footnotes of tables, and in figure or figure captions.

Weights and measures (metric)		General		Mathematics, statistics	
centimeter	cm	Alaska Administrative Code	AAC	<i>all standard mathematical signs, symbols and abbreviations</i>	
deciliter	dL	all commonly accepted abbreviations	e.g., Mr., Mrs., AM, PM, etc.	alternate hypothesis	H_A
gram	g	all commonly accepted professional titles	e.g., Dr., Ph.D., R.N., etc.	base of natural logarithm	e
hectare	ha	at	@	catch per unit effort	CPUE
kilogram	kg	compass directions:		coefficient of variation	CV
kilometer	km	east	E	common test statistics	(F, t, χ^2 , etc.)
liter	L	north	N	confidence interval	CI
meter	m	south	S	correlation coefficient (multiple)	R
milliliter	mL	west	W	correlation coefficient (simple)	r
millimeter	mm	copyright	©	covariance	cov
		corporate suffixes:		degree (angular)	°

ABSTRACT

Since 1988 Alaska Department of Fish and Game (ADF&G) has required varying levels of observer coverage aboard vessels participating in Bering Sea and Aleutian Islands (BSAI) crab fisheries. This report summarizes data collected in the 2011/12 BSAI commercial crab fisheries and the 2011 Pribilof Islands commercial golden king crab fishery by ADF&G crab observers deployed on floating-processor vessels, catcher-processor vessels, and catcher vessels and by ADF&G dockside samplers. Primary data summaries include estimates of catch and catch per unit effort (CPUE) and information about size and shell condition of both discarded and retained crab. Further information about catch rates by soak time and depth, female reproductive condition, sampled pot lift locations, species composition of sampled pot lifts, and legal tally results is provided in a series of appendices.

Key words: Alaska Department of Fish and Game, Bering Sea, Aleutian Islands, crab observer, golden king crab, red king crab, blue king crab, snow crab, Tanner crab.

INTRODUCTION

Regulations (5 AAC 39.645) adopted by the Alaska Board of Fisheries (BOF) grant the Alaska Department of Fish and Game (ADF&G) the full authority and responsibility for deploying onboard observers on any vessel participating in the commercial Bering Sea and Aleutian Islands (BSAI) crab fisheries or in any fishery conducted under a commissioner's permit as necessary for fishery management and data-gathering needs. Those regulations require deployment of observers on all vessels that process snow crab *Chionoecetes opilio*, Tanner crab *C. bairdi*, grooved Tanner crab *C. tanneri*, triangle Tanner crab *C. angulatus*, red king crab *Paralithodes camtschaticus*, blue king crab *P. platypus*, or golden king crab *Lithodes aequispinus*. Those regulations additionally charge ADF&G with deploying observers as needed on catcher vessels participating in commercial BSAI king and Tanner crab fisheries, excluding those of Norton Sound and St. Lawrence Island Sections. Schwenzfeier et al. (2012) provide details on regulations pertaining to the State of Alaska Shellfish Onboard Observer Program and a history of that program from its inception in 1988.

ADF&G observers deployed on fishing vessels in the BSAI crab fisheries record the gear type, location, depth, and soak time of a daily random sample of pot lifts and describe the species composition of their contents, including the sex and legal status of all commercially important captured crabs. For a subset of sampled pot lifts, a range of biological measurements and assessments of all commercially important crabs and selected other species of interest is also obtained. In addition, ADF&G onboard observers and dockside samplers document overall vessel catch and effort, take size-frequency samples, conduct legal tallies, and estimate the average weight of delivered catch. ADF&G Westward Region staff maintain the information collected by observers and dockside samplers in a database that is used in research and management of Alaska's BSAI crab stocks.

This report summarizes data collected by onboard observers and dockside samplers during the 2011/12 Bristol Bay red king crab fishery, 2011/12 Bering Sea snow crab fishery, 2011/12 St. Matthew Island blue king crab fishery, 2011 Pribilof Islands golden king crab fishery, and 2011/12 Aleutian Islands golden king crab fisheries east and west of 174° W long (Table 1). For each of these six fisheries, this report gives estimates of catch per unit effort (CPUE), catch, and size and shell-condition distributions for both discarded and retained crabs. Further information about catch rates by soak time and depth, female reproductive condition, location and species composition of sampled pot lifts, and total legal tally sample results is provided in a series of appendices.

METHODS

Methods described in this report relate to ADF&G observer and dockside sampler data-collection activities and do not reflect all observer and dockside sampler duties. In accordance with the provisions of 5 AAC 39.645, observers were deployed on all floating-processor and catcher-processor vessels participating in each fishery, on all catcher vessels prosecuting the St. Matthew Island blue king crab fishery, on randomly selected catcher vessels participating in the Bristol Bay red king crab and Bering Sea snow crab fisheries, and on the two catcher vessels permitted to harvest Pribilof Island golden king crab during 2011. In the Aleutian Islands golden king crab (AIGKC) fisheries, all catcher vessels were required to carry an observer during harvest of at least 50% of their total harvested weight in each three-month trimester of the nine month season. Dockside samplers were responsible for sampling retained catch delivered by vessels with no onboard observer.

TERMS

For the purposes of this report, terms related to the discussion of sampled crabs and observer sampling duties are defined as follows:

<i>Pot lift sample</i>	A randomly selected pot lift from which captured crab of all species are identified and enumerated. For a subset of these pot lifts, measurements and assessments of ancillary characteristics are also recorded for crab of selected species.
<i>Legal tally</i>	Examination of up to 600 crab randomly selected from the retained catch to assure regulatory compliance regarding the retention of crab by species, size, and sex.
<i>Size frequency sample</i>	Biological measurements of up to 100 randomly selected retained crab for the purpose of determining carapace size and shell condition distribution.
<i>Carapace length (CL)</i>	The biological size measurement of all species of king crabs <i>Lithodes</i> and <i>Paralithodes</i> and hair crab <i>Erimacrus isenbeckii</i> taken as the straight-line distance from the posterior margin of the right eye orbit to the medial-posterior carapace margin.
<i>Carapace width (CW)</i>	The biological size measurement of all species of <i>Chionoecetes</i> crabs taken as the greatest straight-line distance perpendicular to a line midway between the eyes to the medial-posterior margin, not including the spines (cf. <i>Legal measurement</i> , below).
<i>Legal measurement (LM)</i>	The measurement used to determine if male crabs are at or greater than the minimum legal size for retention: the greatest straight-line distance across the carapace of male crabs, including the spines, perpendicular to a line midway between the eyes to the medial-posterior margin (cf. <i>Carapace width</i> , above).
<i>Ovigerous</i>	Bearing a clutch of extruded eggs (pertains only to mature female crabs).

<i>Uneyed eggs</i>	Eggs that are unfertilized or in early developmental stages with no visible eyespots.
<i>Eyed eggs</i>	Eggs in later developmental stages with visible eyespots or prezoaeae.
<i>Barren/matted setae</i>	An egg clutch is not present but previous egg brooding is evidenced by dirty pleopodal setae or the presence of attached dead eggs or empty egg cases.
<i>Barren/clean setae</i>	An egg clutch is not present and there is no evidence of previous egg brooding; pleopodal setae are clean, shiny, light in color, and very fine or, rarely, there are no visible setae on the pleopods. Females assigned this code are usually immature.
<i>Shell condition</i>	A description of the appearance of the crab exoskeleton that is determined by examining characteristics that change or show wear with time since the last molt (Donaldson and Byersdorfer 2005; Jadamec et al. 1999). Observers scored the shell condition of sampled crabs as either “soft,” “new pliable,” “new,” “old,” or “very old” based on shell hardness and color, the nature and extent of abrasions and wear of the shell surfaces, spines, and dactyls, and the number and type of epibionts on the shell surfaces.
<i>Catch per unit effort (CPUE)</i>	The mean catch for a standard unit of fishing effort. In this report CPUE represents the mean catch in number of crab per pot lift.

CRAB OBSERVER SAMPLING DUTIES

During the 2011/12 BSAI commercial crab fisheries, observers were deployed on floating-processor vessels, catcher-processor vessels, and catcher vessels. Observers deployed on floating-processors had access only to previously sorted retained catch from delivering catcher vessels, whereas observers placed on catcher-processor and catcher vessels were able to examine the contents of pot lifts prior to sorting by the crew. The number of pot lifts observers were required to sample on each day of fishing activity varied by fishery and vessel type. In general, pot lift sampling goals, as well as observer ability to attain them, depend on a number of variables unique to each fishery and season, including weather, catch rates, assigned research data collection projects, and the order of sampling priorities established by ADF&G. Fishery specific observer deployments and pot lift sampling goals are outlined in Table 1. In all cases observers were expected to communicate with the vessel skipper and to examine the Daily Fishing Log (DFL) or other records in documenting daily and total catch and effort (number of pot lifts). Comprehensive ADF&G crab observer sampling methods are detailed in the 2011 ADF&G Crab Observer Training and Deployment Manual¹.

¹ Crab Observer Training and Deployment Manual. September 2011. ADF&G Shellfish Observer Program, Dutch Harbor, unpublished.

Floating-Processor Vessels

Observers deployed on floating-processor vessels primarily monitor deliveries from catcher vessels. Sampling duties during each delivery included obtaining a size-frequency sample, conducting a legal tally, and determining average weight of retained crabs.

Catcher-Processor Vessels

Sampling duties for observers deployed on catcher-processor vessels included pot lift sampling, size-frequency sampling, legal-tally sampling, and determination of average weight of retained crab for each day the vessel retained catch. Occasionally, catcher vessels delivered to a catcher-processor vessel. In those situations, the observer sampled the catcher-vessel catch as if deployed on a floating processor. (On rare occasions a catcher-processor vessel will deliver to a shore side processor, in which case the observer assumes the responsibilities of an observer deployed on a catcher vessel.)

Catcher Vessels

The main duty for observers deployed on catcher vessels was pot lift sampling on each day the vessel fished. When the vessel delivered to a processing facility, whether at sea or on shore, the observer obtained a size-frequency sample, conducted a legal tally, and determined average weight of retained crab. If deliveries were made at sea to a floating-processor vessel, all sampling was completed by the observer deployed on the catcher vessel.

DOCKSIDE SAMPLER SAMPLING DUTIES

Dockside samplers were responsible for sampling retained catch delivered to shore-side processors by vessels with no onboard observer. Sampling duties during each delivery included obtaining a size-frequency sample, conducting a legal tally, and determining average weight of retained crabs. Dockside samplers were also required to document trip catch and effort (number of pot lifts) through a confidential interview with the vessel captain and examination of the DFL or other records. A full account of dockside sampler duties is available in the ADF&G Shellfish Dockside Sampling Manual².

ESTIMATION OF CPUE AND TOTAL FISHERY CATCH

With exception of the Aleutian Islands golden king crab fisheries, estimates of CPUE presented here were generated from observer-collected data using a ratio estimator introduced by Gaeuman (2009). In earlier reports different estimates of CPUE were calculated depending on the information available and on varying assumptions about the sampling design. The “sample CPUE” reported before 1997 (e.g., Tracy 1995) was calculated as the simple average catch over all sampled pot lifts. Boyle et al. (1997) introduced stratification by day within vessel, and Burt and Barnard (2003) introduced additional stratification by vessel type (catcher-processor or catcher-only) into the report series.

Inference using the current ratio estimator depends on the fact that within a fishery observers are assigned to all participating catcher-processor vessels and by simple random sampling to a subset of all participating catcher vessels. In addition, it is assumed that sampled pot lifts are selected by simple random sampling from all pot lifts on each vessel fishing day, independently across days.

² Shellfish Dockside Sampling Manual. September 2011. ADF&G Dockside Sampling Program, Dutch Harbor, unpublished.

Under that setup it is straightforward to estimate both total catch and the total number of pot lifts for all vessels based on observed vessel days, treating vessel types as strata, with vessels as primary sampling units within them, and vessel days as strata within vessels, with pot lifts as secondary sampling units within those. The ratio of these estimates of total catch and total number of pot lifts then estimates fishery mean CPUE defined as fishery total catch divided by fishery total effort, i.e. total number of pot lifts. A variance estimator can be developed using standard variance estimators for the component estimators of total catch and total number of pot lifts. Appendix A1 describes both the ratio estimator of CPUE and the derivation of its variance estimator.

For estimation of CPUE in the Aleutian Islands golden king crab fisheries, partial observer coverage on individual participating catcher vessels makes the ratio estimator used for the other BSAI crab fisheries unsuitable. Instead, for these two fisheries overall fishery CPUE is estimated assuming independent simple random sampling of pots on individual vessels, with stratification by vessel and reported vessel proportions of total fishery effort (number of pot lifts) applied as known weights. It should be noted, however, that the lack of any randomization in the specific assignment of observer coverage in these fisheries fundamentally precludes properly valid design-based inference of CPUE or other fishery characteristics.

By contrast with these design-based estimates of CPUE, actual total fishery (ATF) CPUE as reported in annual management reports for commercial crab fisheries in the BSAI management areas (e.g., Fitch et al. 2012) is based on effort and catch information extracted from a combination of fish tickets, daily fishing logs (DFL), and confidential interviews with vessel captains and represents an independent estimate of fishery CPUE³. ATF CPUE estimates, however, are available only for retained legal crab. Estimated total catches reported in this document, as opposed to ATF values, were calculated by multiplying CPUE estimates from observer-collected data by corresponding ATF estimates of fishery pot lift totals.

Cod Pots

In some crab fisheries regulations allow deployment of a specified number of groundfish-configured pots targeting Pacific cod *Gadus macrocephalus* for use as bait (5 AAC 34.825(k) and 5 AAC 35.525(d)). Though some crab are typically captured in these pots, they generally have a much lower CPUE than pots targeting crab and so misrepresent fishing efficiency in the directed crab pot fishery. For this reason, ADF&G crab observers are currently instructed not to sample them, and they are omitted in the estimates of CPUE reported in this document. Cod pots were deployed during the 2011/12 Bristol Bay red king crab and Bering Sea snow crab fisheries and accounted for approximately 5% and 8%, respectively, of all pots lifted during observer pot lift sampling days. Consequently, for these fisheries estimators of CPUE can be expected to be biased slightly high relative to ATF values, which depend on effort totals that do not distinguish between conventional and groundfish-configured pots.

RESULTS

BRISTOL BAY RED KING CRAB

The 2011/12 Bristol Bay red king crab season commenced October 15 and closed January 15. Most fishing occurred early in the season. Total allowable catch (TAC) in this fishery was set at

³ Forrest Bowers, BSAI Area Management Biologist, ADF&G, Dutch Harbor, 2010, personal communication.

7.834 million pounds, with legal male crab at least 6.5 in LM. Two catcher-processors and 60 catcher vessels participated. Onboard observers sampled 698 (1.5%) of the ATF reported total of 45,166 pot lifts (Table 1). Appendix B1 shows locations of sampled pot lifts.

Onboard observers collected CL measurements of 40,212 male red king crab from sampled pot lifts (Figure 1). Average CL was 135.8 mm, and 92.3% of the crab were classified as new shell. CL measurements of 1,752 female red king crab from sampled pot lifts averaged 107.3 mm. Approximately 99.3% of the females were new shell. CL measurements were also recorded for 10,707 male red king crab by onboard observers and dockside samplers in size-frequency sampling of retained catch. Average CL was 148.5 mm, and 88.7% of the sampled crab were new shell.

Estimated fishery CPUE of legal-retained red king crab was 31.0 crab per pot lift (Table 2), with 95% confidence interval (26.67, 35.40), from a t-distribution as detailed in Appendix A. This value, which compares to an ATF reported value of 28.3, is roughly double the 2010/11 estimate of 17.2 and the highest since 2006/07 (Figure 2). Estimated bycatch of discarded sublegal males was nearly as high at 28.8 crab per pot lift; estimated female bycatch was 2.2 crab per pot lift, down slightly from last year's value. Some incidental bycatch of discarded Tanner and snow crab, mostly legal-size males, was also observed in this fishery.

Total catches of all animals identified in sampled pot lifts during the 2011/12 Bristol Bay red king crab season are provided in Appendix C1. Additional appendices contain CPUE by soak time (Appendix C2) and depth (Appendix C3) and the reproductive condition of female red king crab from sampled pot lifts (Appendix C4).

Legal tallies conducted during the 2011/12 season by onboard observers and dockside samplers totaled 16,079 crabs, accounting for 1.3% of the fishery reported harvest (Appendix D1). Approximately 0.27% of all sampled crabs were illegal, all of them sublegal male red king crab.

BERING SEA SNOW CRAB

The 2011/12 Bering Sea snow crab fishery opened October 15 with a TAC of 88.894 million pounds. Legal harvest was restricted to male crab at least 3.1 in LM. (Note that although the minimum legal size for snow crab in this fishery is 3.1 in LM, processing plants generally do not accept crab smaller than 4 in LM.) Whereas the regulatory fishery closure is May 31 in the Western subdistrict (west of 173° W long.) and May 15 in the Eastern subdistrict (east of 173° W long.), the season was extended by emergency order to June 15 west of 171° W long. as a result of unusual sea ice conditions that disrupted fishing activity during much of the season. Two catcher-processor vessels and 70 catcher vessels participated. Onboard observers sampled 2,235 (0.8%) of the ATF reported 270,602 pot lifts (Table 1). Sampled pot lift locations are shown in Appendix B2.

Onboard observers collected CW measurements of 165,344 male snow crab during pot lift sampling (Figure 3). Average CW was 112.1 mm and 90.3% of the crab were categorized as new shell. Average female snow crab CW was 58.7 mm, based on 5,607 measured females, with 70.0% of them judged new shell. CW measurements were additionally recorded on 58,499 male snow crab in size-frequency sampling of retained catch. Average CW was 115.4 mm and 94.0% of the crab were new shell.

Estimated CPUE of legal-retained snow crab was 231.3 crab per pot lift in 2011/12 (Table 3), with 95% confidence interval (211.19, 251.46). Like the 2011/2 ATF reported value of 223.8, it

suggests a continuing decline over the last few years (Figure 4). Average catch per pot for discarded legal-size males, mostly animals smaller than 4 in (~102 mm) CW, also decreased further in 2011/12. On the other hand, estimated 2011/12 female CPUE at 11.1 crab per pot lift was notably high and about 10 times the previous year's rate. As shown in Table 3, observers also documented some bycatch of discarded Tanner crab, mostly legal-size males, along with smaller numbers of crabs considered to be hybrid *Chionoecetes*, including an estimated 50-thousand retained males judged legally retainable by the criteria of 5 AAC 35.521.

Total catches of all animals identified in sampled pot lifts during the 2011/12 season are provided in Appendix C5. Additional appendices contain sampled pot lift CPUE by soak time (Appendix C6) and depth (Appendix C7) and the reproductive condition of female snow crab in sampled pot lifts (Appendix C8).

Legal tallies conducted on catcher-processor vessels and on catcher vessels delivering snow crab to processors totaled 128,155 crabs, which accounted for 0.2% of the reported total catch (Appendix D1). Of those, 0.21% were illegal, most of them non-target Tanner *C.bairdi*. By contrast, most of the illegal crabs encountered in in other 2011/12 BSAI crab fisheries were undersized males of the target species.

SAINT MATTHEW ISLAND BLUE KING CRAB

The St. Matthew Island blue king crab fishery opened for the third consecutive time since 1998 on October 15, 2011 with a TAC of 2.539 million pounds and closed by regulation February 1, 2012, though fishing was completed by the end of 2011. Legal harvest was limited to male crab at least 5.5 in LM. All 18 participating catcher vessels were required to carry an observer (Table 1). Of the ATF reported 48,554 pot lifts in this fishery, observers sampled 3,359 (6.9%). Locations of sampled pot lifts are mapped in Appendix B3.

Observers took CL measurements from 62,868 male and 4,135 female blue king crab in pot lift sampling (Figure 5). Respective average CL values were 117.9 mm and 90.0 mm. Observers recorded 91.3% of the males and 60.7% of the females as new shell. Size-frequency sampling of 4,954 fishery-retained male blue king crab yielded an average CL of 130.0 mm, with 94.3% of the sampled animals judged new shell.

Estimated 2011/12 CPUE of legal-retained crab was 9.4 crab per pot lift (Table 4), with approximate 95% confidence interval (9.22, 9.58). The ATF reported value was slightly lower at 9.0 crab per pot lift. Catch rates in this fishery since its resumption in 2009/10 have been low by comparison to values prior to the 1999 closure (Figure 6). Estimated 2011/12 bycatch of discarded sublegal males slightly exceeded the legal catch, as was true in each of the two previous seasons, whereas estimated female discard CPUE was down from 5.1 in 2010/11 at 1.3 crab per pot lift. Some incidental bycatch of subsequently discarded snow crab occurred in the 2011/12 St. Matthew Island blue king crab fishery, most of it consisting of legal-size males.

Total catches of all animals identified in sampled pot lifts during the 2011/12 season are provided in Appendix C9. Additional appendices contain CPUE by soak time (Appendix C10) and depth (Appendix C11) and the reproductive condition of female blue king crab in sampled pot lifts (Appendix C12).

Legal tallies conducted on catcher vessels delivering blue king crab to processors totaled 22,398 crabs, or 5.1% of the reported harvest (Appendix D1). Approximately 0.41% of the sampled animals were illegal due to size, sex, or species restrictions.

PRIBILOF ISLANDS GOLDEN KING CRAB

This non-rationalized fishery is currently managed using a guideline harvest level (GHL) of 0.150 million pounds under authority of an ADF&G commissioner's permit valid for a calendar year, with legal harvest limited to male crab a minimum of 5.5 in LM. Observer coverage is mandatory during all fishing activity. Because only two catcher vessels made landings in 2011, all information relating to the specifics of fishing activity and observer sampling effort is confidential.

ALEUTIAN ISLANDS GOLDEN KING CRAB

The BOF re-designated the Aleutian Islands king crab registration area in March 1996 by combining two existing areas, Dutch Harbor and Adak, and directed ADF&G to manage golden king crab of the Aleutian Islands east and west of 174° W long. separately as two distinct stocks (Baechler et al. 2012). In 2011/12 both fisheries were open from August 15 to May 15. Legal harvest was restricted to male crab measuring at least 6.5 in LM.

East of 174° W Longitude

Three catcher vessels participated in the 2011/12 Aleutian Islands golden king crab fishery east of 174° W long., where the TAC was set at 3.15 million pounds. Onboard observers sampled 361 pot lifts accounting for 2.0% of the ATF reported 17,915 pot lifts in the fishery (Table 1). Appendix B5 shows sampled pot lift locations.

Average CL of 18,607 male golden king crab measured in pot lift sampling was 146.2 mm, and 97.5% were new shell; average CL of 3,172 measured females was 129.2 mm, and 99.9% were new shell (Figure 8). In size-frequency sampling of 2,507 retained crab, average CL was 153.2 mm, and 98.3% were recorded as new shell.

Estimated legal-retained CPUE was 38.6 crab per pot lift (Table 6), with 95% confidence interval (36.52, 40.74). This value is statistically indistinguishable from the ATF estimate of 37.3, which is higher than the previous record-high CPUE for this fishery (28 in 2007/08; Baechler 2012). By contrast, estimated bycatch rates of sublegal and female golden king crab were in line with historical fisheries (Figure 9). No notable bycatch of any other commercially important crab species was observed in this fishery.

Total catches of all animals identified in sampled pot lifts during the 2011/12 eastern AIGKC crab fishery are provided in Appendix C17. Additional appendices contain CPUE by soak time (Appendix C18) and depth (Appendix C19) and reproductive condition of female golden king crab (Appendix C20) from sampled pot lifts.

Legal tallies conducted throughout the season onboard catcher vessels delivering golden king crab from the eastern Aleutian Islands fishery totaled 8,305 crabs, representing approximately 1.2% of the fishery reported harvest (Appendix D1). Of these, 0.31% were illegal due to size, sex, or species restrictions.

West of 174° W Longitude

A single catcher-processor and 2 catcher vessels participated in the 2011/12 AIGKC crab fishery west of 174° W long., where the TAC was set at 2.835 million pounds. ATF reported effort was 26,326 pot lifts, of which observers sampled 837, or 3.2% (Table 1). Locations of sampled pot lifts are shown in Appendix B6.

Onboard observers recorded CL measurements of 26,081 male and 7,362 female golden king crab captured in sampled pot lifts (Figure 10). Male and female CL averages were respectively 145.9 mm and 137.9 mm. New-shell crab made up 97.0% of the males and 96.9% of the females. Average CL of 10,639 male crab measured in size-frequency sampling of retained catch was 153.4 mm, and 96.3% of them were new shell.

Estimated legal-retained CPUE in this fishery was 22.9 crab per pot lift (Table 7), with 95% confidence interval (21.54, 24.29). As in the eastern AIGKC fishery, this value is consistent with the higher estimated catch rates following crab rationalization (Figure 11) and also close to the ATF reported 23.4 crab per pot lift. Estimates of discarded male and female golden king crab CPUE in the 2011/12 western fishery are likewise consistent with those from other years since rationalization. Observers in this fishery recorded no noteworthy bycatch of other commercially important crab species.

Appendix C21 lists total catches of all animals observed in sampled pot lifts during the 2011/12 western AIGKC fishery. Appendices C22 and C23 give sampled pot lift CPUE by soak time and depth. Appendix C24 characterizes reproductive condition of captured female golden king crab.

Legal tallies conducted onboard catcher and catcher-processor vessels prosecuting the 2011/12 AIGKC fishery west of 174° W long. totaled 18,875 crabs. Sampled crabs made up 3.1% of the ATF reported harvest (Appendix D1). Approximately 0.60% of sampled animals were illegal due to size, sex, or species restrictions.

Table 8 summarizes all 2011/12 BSAI crab fishery observer-based estimates of legal retained CPUE and harvest number in comparison to their ATF reported analogs.

ACKNOWLEDGMENTS

Shellfish observers deployed during the 2011/12 BSAI crab fisheries collected the data summarized in this report. Their diligence in collecting biological and fisheries management information while living and working at sea, often for extended periods and sometimes under extremely challenging conditions, is essential to management of these fisheries.

I thank ADF&G Dutch Harbor staff for answering questions and fulfilling data requests, ADF&G colleagues Carrie Worton, Kim Phillips, Eric Evans, and Doug Pengilly for reviewing this report, and Lindsay Gann and Katherine Greer for generous assistance in the ADF&G publishing process.

Provision of the data for this report was funded in part by the National Oceanic and Atmospheric Administration (NOAA) Awards NA11NMF4370147 and NA12NMF4370099. The views expressed here are those of the author and do not necessarily reflect the view of NOAA or any of its sub-agencies.

**APPENDIX A. ESTIMATION OF CPUE FROM
OBSERVER DATA**

It is here assumed that under the current sampling design, observed vessels are randomly selected independently within each vessel type, as are pot lifts within each day fished by each observed vessel. We first consider vessels of a single type, e.g. catcher vessels. Let

M = number of vessels of given type (catcher-only or catcher-processor) in fishery

m = number of vessels within given type sampled for observation

D_j = number of days fished by vessel j

N_{jk} = number of pots lifted by vessel j on day k

N_j = total number of pots lifted by vessel j over all D_j days fished

N = total number of pots lifted by all vessels of given type during fishery

c_{jkl} = number of crab observed on vessel j on day k in sampled pot l

n_{jk} = number of pots sampled on vessel j on day k

$\bar{c}_{jk} = \frac{1}{n_{jk}} \sum_l^{n_{jk}} c_{jkl}$
 = vessel j sample average number of crab per pot on day k

τ_j = vessel j total catch over all pots and days fished

We want to estimate overall vessel type CPUE $\mu = \frac{\sum_j^M \tau_j}{\sum_j^M N_j}$ (vessel type total catch divided by

total number of pot lifts) from the observer data $\{c_{jkl}\}$. Under independent simple random sampling of pots on each day on each vessel and stratifying by day, the usual stratified estimator of τ_j is

$$\hat{\tau}_j = \sum_k^{D_j} N_{jk} \bar{c}_{jk} \tag{1}$$

with variance estimator

$$\begin{aligned} \hat{V}[\hat{\tau}_j] &= \sum_k^{D_j} N_{jk}^2 \hat{Var}[\bar{c}_{jk}] \\ &= \sum_k^{D_j} N_{jk}^2 \left(1 - \frac{n_{jk}}{N_{jk}}\right) \frac{1}{n_{jk}} \frac{\sum_l^{n_{jk}} (c_{jkl} - \bar{c}_{jk})^2}{n_{jk} - 1} \end{aligned} \tag{2}$$

-continued-

by virtue of standard results (e.g. Cochran 1977). Assuming a simple random sample S of m out of M vessels of the given type, an unbiased estimator of vessel type total catch τ is then simply

$$\hat{\tau} = \frac{M}{m} \sum_j^m \hat{\tau}_j, \quad (3)$$

since, conditioning on S , we have

$$\begin{aligned} E[\hat{\tau}] &= E\left[\frac{M}{m} \sum_j^m \hat{\tau}_j\right] \\ &= E\left[E\left[\frac{M}{m} \sum_j^m \hat{\tau}_j \mid S\right]\right] \\ &= E\left[\frac{M}{m} \sum_j^m E[\hat{\tau}_j \mid S]\right] \\ &= E\left[\frac{M}{m} \sum_j^m \tau_j\right] \\ &= ME\left[\frac{1}{m} \sum_j^m \tau_j\right] \\ &= M \frac{1}{M} \sum_j^M \tau_j \\ &= \sum_j^M \tau_j \\ &= \tau. \end{aligned}$$

Its variance, which may also be obtained by conditioning on the initial sample of vessels, is

given by $Var[\hat{\tau}] = M^2 \left(1 - \frac{m}{M}\right) \frac{1}{m} \frac{\sum_j^M (\tau_j - \bar{\tau})^2}{M-1} + \frac{M}{m} \sum_j^M Var[\hat{\tau}_j]$, where $\bar{\tau}$ denotes the mean of the τ_j . An unbiased estimate of this variance is

$$\hat{Var}[\hat{\tau}] = M^2 \left(1 - \frac{m}{M}\right) \frac{1}{m} \frac{\sum_j^m (\hat{\tau}_j - \bar{\hat{\tau}})^2}{m-1} + \frac{M}{m} \sum_j^m Var[\hat{\tau}_j] \quad (4)$$

with $\bar{\hat{\tau}} = \frac{1}{m} \sum_j^m \hat{\tau}_j$, the average of the observed vessel estimated total catches (Cochran 1977,

Theorem 11.2). Note that if all vessels of the given type are sampled, as is typically true of the catcher-processor fleet, this reduces to $\hat{Var}[\hat{\tau}] = \sum_j^{m=M} Var[\hat{\tau}_j]$. On the other hand, since fishery pot lift totals N_j for each observed vessel are in principle known (e.g. from confidential interviews with vessel captians), an unbiased estimate of the vessel type total number of pot lifts is the simple expansion estimator

$$\hat{\lambda} = \frac{M}{m} \sum_j^m N_j \quad (5)$$

with unbiased variance estimator

$$\hat{Var}[\hat{\lambda}] = M^2 \left(1 - \frac{m}{M}\right) \frac{1}{m} \frac{\sum_j^m (N_j - \bar{N})^2}{m-1}, \quad (6)$$

where \bar{N} is the N_j sample mean, again in accordance with basic results.

For the combined fishery, given estimates $\hat{\tau}_C$ and $\hat{\tau}_{CP}$ of catcher vessel and catcher-processor vessel total catch, an estimate of overall fishery total catch τ_F is simply their sum

$$\hat{\tau}_F = \hat{\tau}_C + \hat{\tau}_{CP}, \quad (7)$$

and under the assumption that sampling of vessels within each type occurs independently, an estimate of its variance is

$$\hat{Var}[\hat{\tau}_F] = \hat{Var}[\hat{\tau}_C] + \hat{Var}[\hat{\tau}_{CP}]. \quad (8)$$

Both of these estimators inherit unbiasedness from their components. In the same way, an estimate of the overall fishery total number of pot lifts and an estimate of its variance are given by

$$\hat{\lambda}_F = \hat{\lambda}_C + \hat{\lambda}_{CP} \quad (9)$$

and

$$\hat{Var}[\hat{\lambda}_F] = \hat{Var}[\hat{\lambda}_C] + \hat{Var}[\hat{\lambda}_{CP}], \quad (10)$$

likewise unbiased under unbiasedness of the individual vessel type estimators. Overall fishery CPUE can then be estimated using the ratio estimator

$$\hat{\mu} = \frac{\hat{\tau}_F}{\hat{\lambda}_F}. \quad (11)$$

To obtain an approximate variance for (11) we first expand it in a first order Taylor series around

$\mu = \frac{\tau_F}{\lambda_F}$ as $\hat{\mu} \cong \mu + \frac{1}{\lambda_F}(\hat{\tau}_F - \tau_F) - \frac{\tau_F}{\lambda_F^2}(\hat{\lambda}_F - \lambda_F)$. Since vessels are selected independently within the two vessel types, taking variances and rearranging things results in

$$\hat{Var}[\hat{\mu}] \cong \frac{M_C^2}{m_C^2} Var\left[\sum_j^{m_C} \left(\frac{1}{\lambda_F} \hat{\tau}_j^C - \frac{\tau_F}{\lambda_F^2} N_j^C\right)\right] + \frac{M_{CP}^2}{m_{CP}^2} Var\left[\sum_j^{m_{CP}} \left(\frac{1}{\lambda_F} \hat{\tau}_j^{CP} - \frac{\tau_F}{\lambda_F^2} N_j^{CP}\right)\right]. \quad (12)$$

The variances on the right side of (12) can be evaluated by conditioning on the initial simple random sample S of vessels within each type. Ignoring for the moment the particular vessel type, this procedure leads to

$$\begin{aligned} Var\left[\sum_j^m \left(\frac{1}{\lambda_F} \hat{\tau}_j - \frac{\tau_F}{\lambda_F^2} N_j\right)\right] &= Var\left[E\left[\sum_j^m \left(\frac{1}{\lambda_F} \hat{\tau}_j - \frac{\tau_F}{\lambda_F^2} N_j\right) \mid S\right]\right] + E\left[Var\left[\sum_j^m \left(\frac{1}{\lambda_F} \hat{\tau}_j - \frac{\tau_F}{\lambda_F^2} N_j\right) \mid S\right]\right] \\ &= Var\left[\sum_j^m \left(\frac{1}{\lambda_F} E[\hat{\tau}_j \mid S] - \frac{\tau_F}{\lambda_F^2} N_j\right)\right] + E\left[\sum_j^m \frac{1}{\lambda_F^2} Var[\hat{\tau}_j \mid S]\right] \\ &= Var\left[\sum_j^m \left(\frac{1}{\lambda_F} \hat{\tau}_j - \frac{\tau_F}{\lambda_F^2} N_j\right)\right] + E\left[\sum_j^m \frac{1}{\lambda_F^2} Var[\hat{\tau}_j]\right] \\ &= m\left(1 - \frac{m}{M}\right) \frac{\sum_j^M (q_j - \bar{q})^2}{M-1} + \frac{m}{M\lambda_F^2} \sum_j^M Var[\hat{\tau}_j], \end{aligned} \quad (13)$$

where $q_j = \frac{1}{\lambda_F} \tau_j - \frac{\tau_F}{\lambda_F^2} N_j$ and $\bar{q} = \frac{1}{M} \sum_j^M q_j$. Appropriate double substitution of (13) into the right side of (12) then gives

$$\begin{aligned} Var[\hat{\mu}] &\cong \frac{M_C^2}{m_C} \left(1 - \frac{m_C}{M_C}\right) S_{qC}^2 + \frac{M_C}{m_C \lambda_F^2} \sum_j^{M_C} Var[\hat{\tau}_j^C] \\ &\quad + \frac{M_{CP}^2}{m_{CP}} \left(1 - \frac{m_{CP}}{M_{CP}}\right) S_{qCP}^2 + \frac{M_{CP}}{m_{CP} \lambda_F^2} \sum_j^{M_{CP}} Var[\hat{\tau}_j^{CP}], \end{aligned} \quad (14)$$

where S_{qC}^2 and S_{qCP}^2 denote the population variances of the quantities q_j^C and q_j^{CP} . Upon replacing these with their sample analogues s_{qC}^2 and s_{qCP}^2 and substituting the estimators determined by (2) for $Var[\hat{\tau}_j^C]$ and $Var[\hat{\tau}_j^{CP}]$ and those in (3) and (5) for τ_F and λ_F , we obtain the variance estimator

$$\hat{Var}[\hat{\mu}] = \frac{M_C^2}{m_C} \left(1 - \frac{m_C}{M_C}\right) s_{qC}^2 + \frac{M_C}{m_C \hat{\lambda}_F^2} \sum_j^{m_C} \hat{Var}[\hat{\tau}_j^C] + \frac{M_{CP}^2}{m_{CP}} \left(1 - \frac{m_{CP}}{M_{CP}}\right) s_{qCP}^2 + \frac{M_{CP}}{m_{CP} \hat{\lambda}_F^2} \sum_j^{m_{CP}} Var[\hat{\tau}_j^{CP}]. \quad (15)$$

-continued-

It should be noted that the overall totals τ_F and λ_F are used in defining the quantities q_j^C and q_j^{CP} and so (3) and (5) are to be used in estimating the latter. With (11) and (15) in hand an approximate $100(1 - 2\alpha)$ percent confidence interval for overall fishery CPUE μ is

$$\hat{\mu} \pm t_{df,\alpha} \sqrt{\widehat{Var}[\hat{\mu}]}, \quad (16)$$

where $t_{df,\alpha}$ denotes the $100(1 - \alpha)^{\text{th}}$ percentile of the t -distribution on df degrees of freedom. In general, we take $df = m_C - 1$, unless all catcher-only vessels are observed, in which case we use the standard normal distribution to determine an appropriate multiplier, i.e. we put $df = \infty$. (Recall that m_C is the number of observed catcher-only vessels in the directed fishery.) Small sample sizes at some levels of the design, underlying skewed pot count distributions, theoretical bias of the ratio estimator, and the use of an approximate variance admittedly give reason for concern about the applicability of standard asymptotic confidence intervals, and future investigation is warranted. Nevertheless, we believe this approach is reasonable and likely conservative rather than otherwise.

As a final note we remark that if the total number of pot lifts λ_F is in fact known, the unbiased estimator

$$\hat{\mu}_u = \frac{\hat{\tau}_F}{\lambda_F} \quad (17)$$

is a natural candidate for estimating fishery CPUE, and an estimate of its variance is easily obtained from (8). However, though ratio estimators such as (11) are in general not design unbiased, in some applications they can perform well in the sense of having smaller mean square error (MSE) than their unbiased counterparts (Lohr 1999, p. 151). For the application at hand we expect vessel catch and vessel pot lift totals to be highly positively correlated and hence that (11) should provide reasonable estimates of the target parameter. Moreover, (11) is robust to undercoverage resulting from failure to sample pots on all days fished by a vessel selected for observation, so long as sampled pots and observed daily pot lift totals are mostly representative of those on unobserved days. The unbiased estimator (17) decidedly lacks this sort of robustness. It should also be observed that although fishery pot lift totals λ_F , as well as λ_C and λ_{CP} , are routinely extracted from fish ticket data, some uncertainty is associated with these values. More importantly, neither that uncertainty nor its relationship to the observer-collected data is readily quantified, rendering problematic the inferential usefulness of those values in this context.

APPENDIX B. LOCATIONS OF SAMPLED POT LIFTS

Appendix B1.—Locations of pot lifts sampled by observers during the 2011/12 Bristol Bay red king crab fishery.
