Symbols and Abbreviations

The following symbols and abbreviations, and others approved for the *Système International d'Unités* (SI), are used without definition in the following reports by the Divisions of Sport Fish and of Commercial Fisheries: Fishery Manuscripts, Fishery Data Series Reports, Fishery Management Reports, and Special Publications. All others, including deviations from definitions listed below, are noted in the text at first mention, as well as in the titles or footnotes of tables, and in figure or figure captions.

Weights and measures (metric)		General		Mathematics, statistics

December 2014

The Fishery Management Reports series was established in 1989 by the Division of Sport Fish for the publication of an overview of management activities and goals in a specific geographic area, and became a joint divisional series in 2004 with the Division of Commercial Fisheries. Fishery Management Reports are intended for fishery and other technical professionals, as well as lay persons. Fishery Management Reports are available through the Alaska State Library and on the Internet: <http://www.adfg.alaska.gov/sf/publications/>. This publication has undergone regional peer review.

ABSTRACT

This report summarizes reported catch and effort information and management actions for Southeast Alaska and Yakutat groundfish fisheries managed by the Alaska Department of Fish and Game in the Eastern Gulf of Alaska Area, with updated information for the period 2011–2014. The department manages groundfish caught in directed and bycatch fisheries. State-managed directed fisheries during this period targeted: sablefish (*Anoploploma fimbria*), demersal shelf rockfish (DSR) (*Sebastes* spp.), black rockfish (*Sebastes melanops*), lingcod (*Ophiodon elongatus*), and Pacific cod (*Gadus macrocephalus*). The state is also responsible for management of lingcod, DSR, and black, blue (*Sebastes mystinus*) and dark (*Sebastes ciliatus*) rockfish in federal waters. The average annual catch of groundfish in Southeast Alaska was 2.9 million round pounds with an annual estimated ex-vessel value of \$6.9 million. Catch includes fish discarded at-sea for species with high mortality after capture, all *Sebastes* and *Sebastolobus* rockfishes (demersal shelf, pelagic shelf, slope, and black rockfishes) and Pacific cod. All other groundfish catch numbers reflect landings only. The 2014 catch only includes landings through October. Sablefish accounted for 72–85% of the ex-vessel value of groundfish in Southeast Alaska during this reporting period. In addition to landings in groundfish and halibut fisheries, an annual average of 44,614 round pounds of groundfish, primarily lingcod and black rockfish, were landed in salmon troll fisheries and 120,614 round pounds of groundfish, primarily sablefish, were landed in surveys (testfish fisheries) conducted by the department and the International Pacific Halibut Commission during this reporting period.

Key words: sablefish, rockfish, lingcod, Pacific cod, flatfish, longline, dinglebar, jig, Southeast Alaska, Yakutat, commercial fishing, Board of Fisheries, groundfish, Annual Management Report

INTRODUCTION

The Eastern Gulf of Alaska (EGOA) regulatory area for groundfish management encompasses all waters from Dixon Entrance (54°30' N latitude) northwestward along the outer coast to 144° W longitude (Figure 1). Seven state groundfish management areas have been established in Southeast Alaska and occur within the Southeast District (Figure 1). The Icy Bay Subdistrict (IBS) was added to the Southeast District in 1999 and includes the waters between 140° and 144° W longitude and waters of Yakutat Bay north of a line at 59° 30' N latitude, extending seaward from Ocean Cape to 140° W longitude. Four of the management areas, East Yakutat (EYKT) Section, Northern Southeast Outside (NSEO) Section, Central Southeast Outside (CSEO) Section, and Southern Southeast Outside (SSEO) Section, are along the outer coast of Southeast Alaska and make up the Southeast Outside (SEO) Subdistrict. The remaining two areas, Northern Southeast Inside (NSEI) Subdistrict and Southern Southeast Inside (SSEI) Subdistrict, are in internal waters. For the purposes of lingcod (*Ophiodon elongatus*) and black (*Sebastes melanops*) rockfish management the southern areas are redefined as two sectors, Southern Southeast Internal Waters (SSEIW) and Southern Southeast Outer Coast (SSEOC) (Figure 2).

The Alaska Department of Fish and Game (department) has management jurisdiction over all groundfish resources within state waters in the EGOA area. State waters include all internal waters of Southeast Alaska and Yakutat Bay, and waters within three miles of shore along the outer coast. In addition, an amendment to the Gulf of Alaska Federal Groundfish Fisheries Management Plan (FMP) defers management of demersal shelf rockfish (DSR) in both state and federal waters in the SEO district (outer coastal waters east of 140° W longitude) to the state. Black and blue rockfish were removed from the FMP in 1998 and dark rockfish in 2009; management responsibility for these species was transferred to the State of Alaska. Lingcod are under state jurisdiction in both state and federal waters.

In addition to having direct management responsibility for certain groundfish species, the Southeast Alaska and Yakutat (Region I) Groundfish Project provides harvest information and other resource data from the adjacent Exclusive Economic Zone (EEZ) to the National Marine

Fisheries Service (NOAA Fisheries) and North Pacific Fishery Management Council (Council) under the terms of a cooperative agreement with NOAA Fisheries. Under this agreement, department staff have the responsibility of collecting, editing, and verifying all fish tickets from the harvest of groundfish and Pacific halibut (*Hippoglossus stenolepis*) landed in Alaska waters. Since May 2006 fish tickets are being entered by processors via e-Landings, a web-based reporting system, and subsequently validated by department staff. The state is also involved in the management of groundfish in the EEZ through the groundfish project leader's participation on the Council's Gulf of Alaska Groundfish Plan Team.

This document provides information on reported harvest, effort, and management for the state-managed groundfish fisheries in Southeast Alaska and includes updates from 2011 through October 2014. The department does not require at-sea observer coverage in EGOA groundfish fisheries. Only limited data on at-sea discards are recorded. Catch and effort data included in this document include DSR, black rockfish, and lingcod harvest for the Eastern Gulf of Alaska state and federal waters and all groundfish species harvested in NSEI and SSEI state waters. The primary state-managed fisheries within the region include sablefish (*Anoploploma fimbria*), demersal shelf rockfish (*Sebastes* spp.), black rockfish, lingcod, and Pacific cod (*Gadus macrocephalus*). By regulation, sablefish can be fished only with longline and pot gear, and state-managed rockfish and lingcod fisheries are restricted to hook and line gear in the Southeast District. Fisheries targeting sablefish or demersal shelf rockfish almost exclusively use longline gear and directed lingcod fisheries use primarily dinglebar troll gear. Flatfish (*Platichthys*, *Lepidopsetta* and *Pleuronectes* spp.) can be harvested with beam trawl gear in limited areas of NSEI and SSEI. Other trawl gear is prohibited unless authorized in a commissioner's permit.

A no-take groundfish marine reserve (Edgecumbe Pinnacles Marine Reserve) is located in Southeast Alaska in a 3.2 nm² area surrounding the Cape Edgecumbe pinnacles off the southwest coast of Kruzof Island (Figure 3). This area was closed to all removals of groundfish in 1998 by the Alaska Board of Fisheries (board) and to halibut and groundfish in 1999 by the Council. This represents the first no-take groundfish marine reserve in Alaska.

An average of 2.9 million round pounds of state-managed groundfish were caught¹ annually in groundfish and halibut fisheries in Southeast Alaska from 2011–2014; the average annual ex-vessel value of these fish was \$6.9 million dollars (Table 1). Groundfish are also landed in commercial salmon troll fisheries (primarily lingcod and black rockfish; Table 2) and in surveys conducted by the department and the International Pacific Halibut Commission (IPHC; Table 3). In 2014, 32,780 round pounds of groundfish were caught in salmon troll fisheries and 114,152 round pounds in testfish fisheries.

LINGCOD

Lingcod are the largest member of the greenling family, attaining lengths up to 152 cm (Mecklenburg et al. 2002). This cold-water species occurs inshore to depths of 475 m from northern Baja California to the Gulf of Alaska (Mecklenburg et al. 2002). Adult lingcod have complex movement patterns that include daily movements within a home range (Tolimieri et al. 2009; Beaudreau and Essington 2011), frequent excursions outside of this home range (Starr et al. 2004), and long distance

¹ Catch includes fish discarded at-sea for species with high mortality after capture, all *Sebastes* and *Sebastolobus* rockfishes (demersal shelf, pelagic shelf, slope, and black rockfishes) and Pacific cod. All other groundfish catch numbers reflect landings only. The 2014 catch only includes landings through October.

migrations (Jagiello 1990; Starr et al. 2004; Stahl et al. 2014b) with some of these movements related to feeding and spawning. Lingcod are sexually dimorphic (Hart 1973; Cass et al. 1990; Love 1996) with females having a larger average size and greater range of lengths than males (Stahl et al. 2014b). Lingcod reach maturity between 3 and 5 years (Richards et al. 1990; Silberberg et al. 2001) with the maximum age estimated for Southeast Alaska at 36 years (unpublished Alaska Department of Fish and Game data). Lingcod have an unusual reproductive strategy where males move into nearshore rocky areas in the fall to set up territories and females move into the area just prior to spawning in the winter. The females lay large egg masses and the males, after fertilizing the eggs, guard the egg mass from predation until hatching (Cass et al. 1990). During the nest-guarding period, males are particularly susceptible to harvest.

FISHERIES DEVELOPMENT AND HISTORY

Prior to 1987, lingcod landed in the Southeast District were captured incidentally in fisheries targeting other species (Gordon 1994). Lingcod comprise a large amount of the bycatch in the directed DSR longline fishery. In some areas and seasons, bycatch rates of lingcod taken in the DSR fishery have exceeded 50%, by weight, of the DSR catch. Lingcod are also taken as bycatch in the salmon troll and halibut longline fisheries.

The directed lingcod fishery has developed steadily since its inception in 1987 when a small fishing fleet using dinglebar gear harvested 163,305 round pounds of lingcod from the NSEO and the northern portion of CSEO management areas. By 1991, the directed fishery catch of 490,873 round pounds was over half of the total catch (Table 4). The directed fishery occurred primarily out of Sitka with major fishing grounds off the outer coasts of Baranof, Chichagof, and Kruzof Islands. In 1995, there was a major expansion of the directed fishery to EYKT, primarily the Fairweather Grounds; that year peak directed fishery harvest occurred with 665,860 round pounds harvested. The largest total harvest of lingcod in commercial groundfish and halibut fisheries occurred in 1991 with 966,842 round pounds landed (Table 4). Since 1990 the directed fishery accounted for over half of the ex-vessel value of commercial lingcod landings, except in 2001 (Table 4). The majority of the directed fishery is prosecuted using dinglebar troll gear. Current commercial guideline harvest levels (GHLs) are set annually by management area and by fishery (Table 5).

REGULATION DEVELOPMENT

Legal gear for lingcod fishing was defined as hook and line in 1994. In 1997, the board prohibited the use of longline gear in the directed fishery. In 2000, legal gear for the directed fishery was defined as mechanical jigging machines, dinglebar troll gear, and hand troll gear, and in the bycatch fisheries as hook and line gear (no pots, trawls or other net gears).

Regulations, including size limits and seasonal and area closures, have been developed for lingcod to preserve their stock structure. In 1989, the board implemented a minimum size limit of 27" for lingcod in an attempt to prevent harvest of sexually immature females. In 1991, a seasonal closure from January 1 to May 31 was implemented inside the surf line to protect nest-guarding males. In 1994, the seasonal closure was changed to December 1–April 30 and the closure line was extended out to 3 miles offshore; beginning in 1997, the seasonal closure was extended until May 16 by emergency order to further protect nest-guarding males. Area closures were also implemented this year for lingcod in Sitka Sound (except as bycatch in the halibut longline fishery) and in the Pinnacles Marine Reserve off of Cape Edgecumbe (located on Kruzof Island). In 2006, a regulation was adopted that prohibits lingcod from being taken by spear or while using diving gear

from December 1 through May 15. In 2000, the board limited the directed fishery season and retention of lingcod by salmon trollers to May 16 through November 30.

Lingcod have been managed using guideline harvest ranges (GHR) and fishery allocations since the early 1990s. In 1991 a GHR of 300,000–500,000 round pounds was established for the Southeast District (east of 137° W longitude) based on catch histories in the CSEO fishery. In 1994, the department met with industry representatives, including directed commercial fishermen, longliners, and trollers, and developed a lingcod management plan to present to the board. Using a habitat-based approach, GHRs were set on an assumption of 0.25–0.50 mt (metric tons) of lingcod biomass per square nautical mile of rocky habitat for each management area. Seasonal and area allocations were also set for the directed and salmon troll commercial fisheries in CSEO and NSEO. In 2000, lingcod harvest was allocated between fishing sectors and areas, the sport harvest was included in the total GHL, and GHRs were reduced; in addition, a regulation was put into place allowing the department to set trip limits for the directed lingcod fishery by emergency order to promote an orderly fishery and for stock conservation. In 2003, the board provided for a small allocation of lingcod to the black rockfish jig fishery. In 2006, a regulation was implemented that increased the upper end of the GHR for EYKT from 200,000 to 225,000 round pounds with the increase allocated to the directed fishery; 5AAC 28.165(a)(2)(A) stipulates how the EYKT GHL is allocated.

The department has managed lingcod bycatch through regulations set by the board and through emergency orders. In 1994, the board limited lingcod bycatch in the halibut fishery to 5%. In 1997, the lingcod bycatch allowance in the DSR longline fishery was increased from 20% to 35%. The board implemented regulations to allow the department to set groundfish bycatch limits by emergency order in the salmon troll fisheries in 2003 and in the halibut fishery in 2009 in order to maintain the area harvest allocations of lingcod in these fisheries:

1. The lingcod fishery was expanded in 2000 when the western boundary of the Eastern Gulf of Alaska (Southeast District) was extended to include Icy Bay Subdistrict, (waters from 140° W to 144° W longitude). Lingcod allocations were established for the commercial longline and salmon troll fisheries as well the sport fishery. In 2003, the board provided for development of a super-exclusive directed lingcod fishery. Lingcod allocations from the commercial longline and troll fisheries were combined into one commercial allocation (66.66% of the GHL) and made available to each gear group until the annual commercial GHL was taken. In order to accommodate for differences in fishing seasons between commercial sectors, in 2012 the board divided the combined commercial allocation into individual allocations for the directed, longline, and salmon troll fisheries. In 2006, the bycatch allowance of lingcod in the halibut fishery in IBS was increased from 5% to 10%.
2. In 2000, the southern groundfish management areas in Southeast Alaska were redefined for lingcod management as follows: SSEOC includes all waters of the SSEO Section and waters of the SSEI Subdistrict that are south of 56° 00' N latitude and west of Prince of Wales Island or south of 54° 43' N latitude and west of 132° 00' W longitude; SSEIW Sector includes all waters of the SSEI Subdistrict not included in the SSEOC Sector (Figure 2).

The department monitors lingcod fisheries through logbooks, fish tickets, and fishery registrations. In 1994, a mandatory logbook program was established. Registration for the directed fishery registration was required in 2000.

STOCK ASSESSMENT AND MANAGEMENT

The department does not have a stock assessment for lingcod and is not currently able to reliably estimate lingcod biomass or abundance in Southeast Alaska. Lacking abundance estimates, and given the complex life history and behavior of lingcod, impacts to lingcod populations from fishing are difficult to assess. Analysis of catch per unit effort data (CPUE), in terms of fish per hook hour for 1988–1998, showed a decline in CPUE ranging from 21% to 62% in areas where a directed fishery and increased recreational catch had developed. As a result, the GHRs for lingcod were reduced in all areas beginning as early as 1995. Current lingcod GHRs were established by the board in 2000. After these reductions in the GHRs, CPUE began to increase in CSEO until around 2007; since then CPUE has decreased (Figure 4). In NSEO and SSEOC management areas, in some years participation in the directed fishery was low; these data are confidential if there were less than 3 participants. CPUE has been generally stable in NSEO since reductions in GHRs (Figure 4). In SSEOC, CPUE was highly variable from 1994 to 2003 (Figure 4). Since then, data are only available for 3 years (2006, 2010, and 2012); participation in this fishery is too erratic to characterize CPUE in this area (Figure 4). In EYKT, CPUE was variable between 1994 and 2000 while harvest fluctuated dramatically (Figure 4); during this time, CPUE dropped in years following high harvests. After the GHR was reduced in 2000, the CPUE was fairly stable in EYKT; however, in the last three years, the CPUE has been the lowest since 2000 (Figure 4). The CPUE in EYKT is high relative to other management areas (Figure 4), likely because fishing is concentrated in a smaller area where there are typically higher abundances of lingcod (i.e., the Fairweather Grounds). In IBS, the directed fishery was opened in 2003; however, data for that season are confidential due to few participants in the fishery. The CPUE in IBS was stable between 2004 and 2009 and increased from 2010 to 2014 (Figure 4). Recent increases in CPUE in IBS may indicate an increase in lingcod stocks or be a result of changing fishery dynamics—vessel participation has decreased with experienced fishermen remaining in this area.

The department initiated a tag release study for lingcod in 1996 with the goal of obtaining a better understanding of the movement patterns of local lingcod stocks. To date, over 9,188 lingcod have been tagged and 497 tags have been recovered. The lingcod tagging data (through 2011) have been analyzed and summarized in a published report (Stahl et al. 2014b). Net movements of lingcod recaptured in this tagging study were similar to results of other studies with the majority of recaptured lingcod recovered close to their release location (55% within 5 km) and a small proportion of the lingcod recovered at great distances (8% >50 km) (Stahl et al. 2014b). Tagging of lingcod continues on a limited basis.

2011–2014 SEASONS SUMMARY

Directed lingcod harvest has been stable during the 2011–2014 reporting period, ranging from 208,715 to 290,956 round pounds (Table 4). The number of permits issued for directed fishing ranged from 30 to 50, and the directed fishery composed 61–67% of the total harvest of lingcod in all groundfish and halibut fisheries (2011 directed harvest is confidential and not included; Table 4). Lingcod bycatch in the salmon troll fisheries has been relatively low in this reporting period with the exception of 2012, which was almost double the other years and more similar to lingcod bycatch levels observed in salmon troll fisheries prior to 2009 (Table 6). Longline bycatch was high in 2012 and 2013 due to more lingcod taken in the directed DSR fishery, which was open to fishing in more areas in those years (Table 6).

2015 SEASON OUTLOOK

In 2015, similar participation is expected for the directed fishery for lingcod. In addition, lingcod will be taken as bycatch in salmon troll and halibut and DSR longline fisheries. However, the amount of annual lingcod harvest is influenced by a variety of factors including lingcod dock price, which affects participation in the directed fishery, the quota in the halibut fishery, directed DSR fishing opportunities in the SEO.

ROCKFISHES AND THORNYHEADS

More than 30 species of rockfishes are landed in Region I groundfish fisheries from the genera of *Sebastes* and *Sebastolobus*. *Sebastes* rockfishes are divided into three assemblages for management purposes, because species within an assemblage have similar habitat preferences and behavior. The DSR assemblage is comprised of seven nearshore, bottom-dwelling species and includes yelloweye (*S. ruberrimus*), quillback (*S. maliger*), tiger (*S. nigrocinctus*), china (*S. nebulosus*), canary (*S. pinniger*), copper (*S. caurinus*), and rosethorn (*S. helvomaculatus*) rockfish. The pelagic shelf rockfish (PSR) assemblage is comprised of six nearshore schooling species, including black (*S. melanops*), dark, blue, dusky (*S. variabilis*), dark, blue, yellowtail (*S. flavidus*) and widow (*S. entomelas*) rockfish. Prior to 2004, the dusky and dark rockfishes were considered one species and known as *S. ciliatus* (Orr and Blackburn 2004). The slope rockfish assemblage is found along the edge of the continental shelf and on the continental slope in deep water. This group is defined by regulation as any species of the genus *Sebastes* not specified in the DSR or PSR assemblage. The predominant commercial species in this assemblage are rougheyeye (*S. aleutianus*), shortraker (*S. borealis*), and redbanded rockfish (*S. babcocki*). The shortspine thornyhead (*Sebastolobus alascanus*) rockfish is captured in waters from 17 m to as deep as 1,524 m (Mecklenburg et al. 2002); for the purpose of this report, data on this species will be summarized with the slope rockfish assemblage which includes deep dwelling *Sebastes* species.

DEMERSAL SHELF ROCKFISHES

All DSR are considered highly K-selective (i.e., species life history characteristics include slow growth, late maturity, and longevity; Adams 1980, Gunderson 1980, Archibald et al. 1981) and have low estimates of natural mortality (i.e., 2%). Fishes with these life history characteristics are highly susceptible to over-exploitation and are slow to recover once driven below the level of sustainable yield (Leaman and Beamish 1984; Francis 1985). An acceptable exploitation rate for such species is assumed to be low; the department manages the DSR fishery at an exploitation rate (F) equal to natural mortality (2%).

Yelloweye rockfish, the dominant species in the DSR assemblage (in terms of numbers and biomass of catch), occur from northern Baja California to the Aleutian Islands in nearshore waters to 549 m (Mecklenburg et al. 2002). Yelloweye rockfish have been recorded up to 96 cm in length (unpublished Alaska Department of Fish and Game data) and to a maximum reported age of 121 years (Brylinsky et al. 2007). These fish are generally associated with rock habitat (i.e., rocky reefs, ridges, and pinnacles) and tend to be resident; tag return information indicates that adults may stay in the same area over multiple years (O'Connell 1991). Due to these life history traits, yelloweye rockfish populations are susceptible to overharvest and localized depletion.

FISHERY DEVELOPMENT AND HISTORY

DSR have been the target of a directed shore-based longline fishery in Southeast Alaska since the late 1970s. The fishery began in the Sitka Sound area as a small family-run, fresh-fish business, catching primarily black rockfish from skiffs using automatic jigging machines. By 1982, longline gear had replaced jigging machines. The use of longline gear in the fishery changed the dynamic and target species of the fishery, and the catch became predominately yelloweye and quillback rockfish. Harvest increased six-fold in five years with total catch exceeding one million round pounds in 1986. Prior to 1984 well over half of the total Southeast Alaska rockfish landings were reported from CSEO. As effort and harvest continued to increase, much of the effort shifted into SSEI followed by a shift in the late 1980s to SSEO. A directed DSR fishery developed in EYKT in 1991, primarily targeting yelloweye rockfish on the Fairweather Grounds.

The directed DSR fishery harvest has declined since 1987 when 2.7 million round pounds with an ex-vessel value of \$1.4 million was harvested. The lowest harvests occurred in 2006 and 2007 when less than 6,000 round pounds were harvested due to the directed fishery closure in SEO (Table 7). The number of directed permits fished for DSR was highest in 1992 (149 permits); the fewest permits were fished in 2006 and 2007 when directed fishing occurred only in inside waters due to the closures in SEO. Total reported landings of DSR for all groundfish and halibut fisheries was highest in 1987 with 3,300,563 round pounds harvested and lowest in 2014 (harvest only through October) when only 287,818 round pounds were harvested (Table 7). The majority of the DSR harvested in Southeast Alaska has occurred in EYKT, CSEO, and SSEO; DSR harvest in internal waters has occurred on much smaller scale (Figure 5).

Area closures have occurred in some years due to stock conservation concerns. The department has not opened the directed fishery in NSEO since 1994 when the stock assessment survey in that area indicated a low abundance of fish. The EYKT fishery was not opened in 2002 and 2003 because of high levels of estimated DSR mortality in the halibut fishery; this area was also closed to fishing in 2006–2007 and 2010–2011. This area has been open to directed fishing in the last three years (2012–2014). The CSEO area was open to directed fishing in 2012–2013; prior to these years, this fishery had been closed since 2004 and was closed again in 2014. The directed fishery in SSEO was closed in 2005–2007 and again in 2014.

REGULATION DEVELOPMENT

The state has regulated the harvest of DSR in Southeast Alaska since the 1980s. Prior to 1989, the fishery occurred primarily in CSEO where a 1.3 million round pound harvest cap was placed in 1984. In 1987, GHs for the directed DSR fishery were first set by management area under a draft management plan, and directed commercial fishing for DSR was closed in a portion of Sitka Sound after public testimony emphasized the concern regarding localized stock depletion. In 1989, legal gear for DSR was defined as hook and line only.

Regulations were implemented with the development of the directed DSR fishery to improve the market for landings by the small-boat commercial fleet. In the 1980s, the fishery was opened October 1; however, in 1989, the directed fishery was split into 3 periods (1 for SEO and 2 for inside waters) to facilitate marketing of fresh product over an extended portion of the year. In addition, a trip limit of 7,500 round pounds per 5-day period was implemented to preserve DSR as a fresh product. In 1993, DSR were reapportioned by season to allow more fish to be harvested in the winter season when the price was best.

The directed fishery season was curtailed in the summer of 1990 and again in the summer and fall of 1991 when the prohibited species cap for halibut (halibut bycatch mortality cap in non-halibut fisheries) was met. In 1991, the Council set aside a separate allocation of halibut bycatch mortality for the DSR fishery that prevented the directed DSR fishery from being impacted by halibut bycatch mortality in other Gulf of Alaska fisheries.

In 1989, prior to the development of a stock assessment for DSR in SEO, the Council implemented a total allowable catch (TAC)² of 470 mt for all fishery removals of DSR in the SEO district based on the historical fishery harvest in the area. In 1991, the Council extended the waters of SEO from 137° W longitude to 140° W longitude in order to include the EYKT section; state management authority was extended to this area as well. To allow the state to manage DSR harvest within the federal TAC, the department lowered GHs for DSR in all management areas in SEO and a directed fishery harvest limit for DSR in EYKT was implemented. Trip limits were set at 12,000 round pounds for EYKT and reduced from 7,500 to 6,000 round pounds in the other management areas. In addition, closures to directed commercial fishing were implemented for areas surrounding the ports of Sitka, Craig, and Ketchikan.

The DSR fishery in SEO has been managed since 1993 using a TAC that is based on a harvest rate applied to a biomass estimate (O'Connell and Carlile 1993, O'Connell and Brylinsky 2001). The directed DSR fishery was managed with separate seasons following the implementation of the halibut individual fishing quota (IFQ) fishery. In 1997, regulations were adopted to reflect this management with 67% percent of the TAC allocated to the winter fishery season and 33% to the fall fishery season. In 2006, the board allocated the DSR TAC between commercial and sport sectors with 84% to commercial and 16% to sport, and in 2009, the board adopted a proposal to deduct the subsistence catch from the DSR TAC prior to the allocation between the commercial and sport sectors. In 2006, regulations were adopted that restricted the SEO DSR fishery to the winter season only and prevented the directed DSR fishery from overlapping with the IFQ halibut season.

In 1997, an annual guideline harvest level for directed DSR fisheries in SSEI and NSEI was established and set at a level not to exceed 110,000 round pounds in each area.

The DSR fishery in internal state waters continues to be managed using a GH which is split between a fall and winter fishing season. The annual GH is set at 55,125 pounds, half of the allowable limit.

Regulations have been developed to reduce the at-sea discard of DSR due their high post-release mortality caused from their exposure to pressure changes experienced between catch depth and surface waters. Full retention was required of all DSR captured in state waters of Southeast Alaska in 2000; this requirement was restricted to groundfish and halibut fisheries only in 2009. In state waters, a CFEC (Commercial Fisheries Entry Commission) permit holder must retain, weigh, and report all DSR taken; those in excess of the allowable bycatch limits shall be reported as bycatch overage on a fish ticket. Proceeds from the sale of excess DSR are forfeited to the State of Alaska. DSR in excess of legal bycatch limits may be retained for personal use or donated. In addition, there are restrictions on the use of yelloweye rockfish for bait; only the head, tail, fins, and viscera from delivered and processed yelloweye rockfish may be used as bait.

² The federal TAC is set in metric tons (mt); the department sets fishery quotas (GHR, TAC, AHO) in round pounds (round pounds).

Full retention of DSR has been required in groundfish and halibut fisheries in federal waters since 2005. DSR bycatch overage taken in federal waters cannot enter commerce.

The department monitors the directed DSR fishery through logbooks, fish tickets, and fishery registration. In 1989, the department began requiring logbooks for directed fishing of DSR, and in 1990, a DSR directed fishery CFEC interim use permit card for Southeast Alaska was introduced. However, this permit card was not used in EYKT until 1991 when the SEO district was extended to include this area. Since 2003 fishermen have been required to register prior to participating in the directed DSR fishery.

STOCK ASSESSMENT AND MANAGEMENT

The department conducts a multi-year stock assessment survey for DSR in the Southeast District. Biomass is estimated by management area as the product of yelloweye rockfish density, the area of rocky habitat within the 100-fathom contour, and the yelloweye rockfish average weight (O'Connell and Carlile 1993, Brylinsky et al. 2007). Yelloweye rockfish density for the annual stock assessment is based on the most recent estimate by management area; these densities are multiplied by the average weight of yelloweye rockfish from the directed and halibut longline fisheries for the current year and management area.

Yelloweye rockfish density is estimated using distance sampling methods along line transects. A submersible was used to survey yelloweye rockfish until 2009; however, due to changes in the availability of a cost-effective submersible, the department began conducting line transects with an ROV (remote operated vehicle) in 2012. Analysis of data obtained from ROV and submersible surveys indicates that the ROV is an appropriate survey tool to assess yelloweye rockfish stocks and provides estimates that are comparable to those produced with the submersible. Two of the four SEO management areas have been surveyed with the ROV; CSEO in 2012 and SSEO in 2013. Yelloweye rockfish density was estimated at 752 ye/km² in CSEO and 986 ye/km² in SSEO. In 2014, the department had planned to survey EYKT with the ROV; however, the survey was cancelled due to poor weather. The last survey conducted in EYKT was in 2009 using the submersible; the density of yelloweye was estimated at 1,930 ye/km². The NSEO management area was last surveyed with the submersible in 2001; however, sample sizes were too low to produce valid density estimates that year. The last reliable density estimate of 765 ye/km² for NSEO was obtained in 1994.

The allowable biological catch (ABC) for the DSR assemblage in SEO is set by multiplying the lower bound of the 90% confidence interval of yelloweye rockfish biomass for the region by the natural mortality rate (0.02) and adjusting this estimate by 2–4% to account for the composition of other species in the DSR assemblage. This method is more conservative than using $F_{40\%}$ (0.026) to determine the ABC. The overfishing level is set using a rate of $F_{30\%}$ (0.032). There is no stock assessment information available for NSEI and SSEI management areas where the GHl has historically been set annually at 55,125 round pounds for each area or approximately at the midpoint of the GHR (110,000 round pounds).

Overall, yelloweye rockfish biomass has been decreasing in the Southeast District despite a conservative harvest strategy. Management for this species has been improved with increased accounting of total DSR removals in 2004 and allocation of the resource between sport and commercial sectors in 2006. The stock is not considered overfished, but due to the life history characteristics of this long-lived species and infrequent stock assessment surveys, changes in yelloweye rockfish biomass may not be detected quickly.

2011–2014 SEASON SUMMARY

During this period, quotas were set annually by management area based on the DSR stock assessment and projection of DSR catch in the halibut fishery. The directed fishery was only opened for a management area if the quota was large enough to prosecute an orderly fishery.

During the 2011–2014 reporting period, directed fishing was open in EYKT (2012–2014), CSEO (2012–2013) and SSEO (2011–2013). The DSR harvest in the Southeast District was highest in 2013 with 318,612 round pounds in the directed fishery and 542,787 round pounds in all groundfish and halibut fisheries combined (Table 7). The largest directed fishery allocations and values occurred in 2012 and 2013 with approximately 400,000 round pounds allocated (Table 8) and values of approximately \$500,000 per year (Table 7). During this reporting period, the average price per pound for directed yelloweye rockfish varied from a low of \$1.64 per round pound in 2013 to a high of \$2.10 per pound in 2014. The number of active directed fishing permits ranged from 12 to 25 permits during this period (Table 7).

2015 SEASON OUTLOOK

The most recent version of the DSR stock assessment presented to the Council's *Gulf of Alaska Groundfish Plan Team* in November 2014 recommended an ABC of 225 mt, and a TAC of 217 mt for 2015 (Green et al. 2014). The TAC was set after deducting the subsistence catch (8 mt) from the ABC. This is a 19% reduction from the TAC established in 2014 (Green et al. 2013). The TAC is apportioned 84% to commercial fisheries and 16% to sport fish fisheries, which results in a commercial TAC of 182 mt and a sport TAC of 35 mt (Green et al. 2014). At the time of publication of this document, it was not determined whether SEO directed DSR fisheries would open in 2015. Directed fisheries are opened if, after accounting for mortality in other fisheries, there is sufficient DSR resource available to conduct an orderly fishery and there are no area-specific conservation concerns. This decision will be made in January, after the 2015 halibut quotas have been announced and the associated DSR bycatch is estimated.

PELAGIC SHELF, SLOPE ROCKFISHES, AND SHORTSPINE THORNYHEADS

FISHERY DEVELOPMENT AND HISTORY

Black rockfish compose the largest proportion of the landings for the PSR assemblage both in inside and outside waters in Southeast Alaska. Black rockfish are taken primarily as bycatch in longline and troll fisheries however there is a directed black rockfish fishery that occurs in the SEO. In inside waters, PSR harvest peaked in 1992 and has since been declining (Table 9). Harvest levels have been relatively low in recent years and have varied from 186 round pounds in 2012 to a high of 26,315 round pounds in 1992 (Table 9). In the past 10 years, effort has been low in the directed black rockfish fishery in SEO; harvest peaked in 2003 with 88,465 round pounds and has been as low as 440 round pounds in 2011 (harvest is confidential in some years; Table 10). Harvest in the directed fishery has composed 7–85% of the total harvest of black rockfish in SEO (excluding years where directed harvest is confidential).

In 1999, the Council removed black and blue rockfish from the FMP, and in 2009, dark rockfish were removed as well. The state now has sole management responsibilities for black, blue, and dark rockfish in state and federal waters.

Slope rockfishes and shortspine thornyheads are captured incidentally in longline fisheries for sablefish, halibut, and DSR with the majority of the catch associated with the SSEI and NSEI sablefish fisheries (Table 11). In addition, slope rockfish were targeted by a few fishermen prior to 2003 (Table 11). In 2014, shortspine thornyhead accounted for 45% of the landed slope rockfish bycatch, followed by shortraker rockfish (30%), rougheye rockfish (14%), and redbanded rockfish (9%).

REGULATIONS

Full retention regulations adopted at the 2000 board meeting require that all rockfish caught in internal waters be weighed and reported on fish tickets. Proceeds from the sale of rockfish in excess of legal landing limits are forfeited to the State of Alaska.

In 2003, the board prohibited directed fishing for slope and thornyhead rockfish (*Sebastolobus* spp.). These rockfish may only be captured as bycatch or in directed fisheries under the terms of a commissioner's permit.

Directed fishing for black rockfish is open year round and fishery is prosecuted only in outside waters of the Southeast District. Directed fishing is prohibited in NSEI and SSEIW along with 5 areas along the outer coast. Gear is limited to mechanical jigging machines and dinglebar and hand troll gear. In 2009, the board adopted a proposal which repealed the prohibition on the sale of black rockfish taken as bycatch in waters that are closed to directed black rockfish fishing.

STOCK ASSESSMENT AND MANAGEMENT

The directed black rockfish fishery is managed using area GHs, vessel registrations, gear restrictions and small area closures. This fishery focuses on fishing in nearshore, shallow water rock "reef" habitat: an area traditionally very difficult to assess. There have been no stock assessment surveys to assess black rockfish since 2002. Surveys were conducted to tag black rockfish from 1999 to 2002 with 4,659 black rockfish tagged and released with 58 tags recovered (Tydingco and Brylinsky 1999).

No surveys are performed to assess slope and thornyhead rockfish stocks; however, these species are captured incidentally on annual sablefish longline surveys.

2011–2014 SEASON SUMMARY

The PSR harvest has been variable in both outside and inside waters during this reporting period (2011–2014). During this time period, NSEI and SSEI, harvest levels fluctuated from 186 round pounds to 5,346 round pounds (Table 9). Black rockfish harvest in SEO has ranged from 440 to 9,303 round pounds (harvest in 2014 is confidential) in the directed and 6,732–38,297 round pounds in all groundfish, halibut, and salmon troll fisheries between 2011 and 2014 (Table 10). The number of permits fished in the directed black rockfish fishery ranged from two to six (Table 10) between 2011 and 2014.

The total catch of slope rockfishes and thornyheads in NSEI and SSEI has remained low during this reporting period with under 200,000 round pounds harvested. The highest harvest during this time was in 2012 with 150,678 round pounds (Table 11).

2015 SEASON OUTLOOK

Similar amounts of slope rockfish, thornyheads and PSR are expected to be landed as bycatch in 2015. Effort is expected to be relatively low in the directed black rockfish fishery in 2015; however, it is hard to predict how many permit holders will participate in this fishery, considering the variable participation in recent years. Fishing effort may relate to a number of economic factors, including the market value for black rockfish and fuel prices.

SABLEFISH

Sablefish occur in the northeastern Pacific Ocean from Baja, California to the Aleutian Islands and into the Bering Sea (Mecklenburg et al. 2002). Adult sablefish inhabit the deep-water continental shelf, slope, and coastal fjords. Most adults live in depths of 200 to 500 fathoms but have been captured in depths as great as 1,000 fathoms (Allen and Smith 1988). Sablefish are long-lived and have been recorded at 97 years in Alaska waters (D. Anderl, NOAA fisheries, personal communication); however, few fish greater than 20 years of age are captured in Southeast Alaska commercial fisheries (Mueter 2010). Sablefish are the most valuable groundfish in Southeast Alaska with an ex-vessel value of \$4,776,585 in 2014 and a peak ex-vessel value during this reporting period of \$7,586,700 in 2011.

FISHERY DEVELOPMENT AND HISTORY

State managed fisheries currently occur in NSEI (Chatham Strait) and SSEI (Clarence Strait and adjacent waters of Dixon Entrance). Sablefish have been harvested in the internal waters of Southeast Alaska since the early 1900s. Prior to the 1940s, sablefish were primarily landed as bycatch in the halibut fishery (Bracken 1983). Halibut longline gear was modified in the late 1940s to target sablefish. Until the 1970s, harvest levels fluctuated widely due to low price and better opportunities in other fisheries. Pot gear was first introduced in 1970 in the Clarence Strait and Dixon Entrance areas and the pot fishery accounted for 33% of the total harvest in the early 1970s. In 1981, the NSEI fishery was restricted to longline gear only, but pot gear was still allowed in the SSEI Subdistrict.

Sablefish have been historically managed with limitations on fishing seasons and harvest levels. Season limitations were first imposed in 1945 for the NSEI management area and in 1982 for the SSEI management area (Bracken 1983). Fishing seasons continued to be shortened in both areas as effort escalated in the 1970s and 1980s. GHRs based on historic catches were established for both areas in 1980. In 1985, a limited entry program was implemented for both the NSEI and SSEI sablefish fisheries. However, the number of vessels and overall operating efficiency of the longline fleet increased significantly after the limited entry program was implemented. In order to stay within GHRs, the department continued to reduce the number of fishing days in both areas. In the NSEI area, the number of fishing days fell from 76 days in 1980 to one day in 1987 (Table 12). One-day openings continued in the NSEI area through 1993. In 1993, the NSEI fleet harvested 3,640,000 dressed pounds, which was 2,140,000 dressed pounds over the upper bound of the GHR (1,500,000 dressed pounds). In an effort to improve management, the board adopted an equal quota share (EQS) system for the NSEI area in 1994. In SSEI, the number of fishing days declined from 200 days in 1980 to 2 days in 1996 (Table 13). In 1997, at the request of industry, the board adopted a similar EQS system for the SSEI fishery and established separate seasons for the longline and pot fisheries to reduce gear conflicts.

REGULATIONS

Management regulations, including annual harvest objectives (AHOs), fishing seasons, and gear specifications, are defined separately for the NSEI and SSEI sablefish fisheries. No sablefish fishery occurs in the state-managed 0–3 mile zone in outside coastal waters of Southeast Alaska. The EQS system requires the department to divide the AHO equally among the CFEC permits eligible for each fishery. In 2003, the board adopted regulations allowing fishermen to apply a 5% overage or a 5% underage from the previous year to the current year's EQS in an effort to reduce discard mortality and to acknowledge the difficulties in landing exact amounts of fish. Sablefish may no longer be harvested for use as bait.

The SSEI longline fishery is open annually between June 1 and August 15 and the SSEI pot fishery from September 1 to November 15. The SSEI directed fishing seasons are split to avoid possible gear conflicts. The NSEI longline fishery is open annually between August 15 and November 15. In 2003, new regulations allowed for an off-season fishery in the NSEI area in an effort to collect biological data on sablefish residing in NSEI during winter and spring months. The department chartered longline vessels to conduct a survey in January and February of 2004 and 2005 as part of a research project to observe CPUE rates and collect biological data during the winter. However, winter fishing has not occurred since 2005, because the AHO must be announced prior to off-season fishing, and typically the NSEI stock assessment is not completed until June or July. In 2010, under the same regulation, the department implemented a program to allow NSEI permit holders to retain their PQS during the department longline survey conducted in the summer prior to the start of the commercial fishery season in an effort to decrease department testfish removals. This program reduces the testfish decrement to the ABC, and thus increases the AHO for all permit holders.

STOCK ASSESSMENT AND MANAGEMENT

In 1988, the department began annual longline research surveys in both NSEI and SSEI to assess the relative abundance of sablefish over time using fixed survey stations. Research at the time indicated some movement of sablefish into and out of NSEI and substantial movement into and out of SSEI. Consequently, the department has conducted surveys a few weeks prior to the start of each fishery to examine relative abundance and sablefish population composition near the time of these fisheries. During the annual longline surveys, biological data are collected on sablefish and include length, weight, sex, stage of maturity and otoliths (aging structures). These data are used to describe the age and size structure of the populations and detect recruitment events.

The longline surveys were designed as random stratified surveys; fixed stations were placed in sablefish habitat (based on depth) in Clarence and Chatham Strait where the majority of the commercial SSEI and NSEI fishery harvest occurred. For the SSEI survey, stations were added in Dixon Entrance in 1996 to reflect changes in the fishery distribution. In 2013, the SSEI longline survey was redesigned to improve the spatial coverage of the survey relative to the fishery; the fishery had further shifted into Dixon Entrance with only a few survey stations located in this area. Survey stations were re-allocated in proportion to sablefish habitat by strata. Statistical areas were included in the survey design if a minimum average of 3% (or greater) commercial harvest occurred in the area from 2003 to 2012 (Stahl et al. 2014a).

Since 2000, the longline survey hook spacing, gear soak time, and bait type and size have been standardized to the specifications used in the federal longline survey to allow for comparisons of

stocks in federal and state waters. The hook spacing was 1.6–1.8 m from 1997 to 1999; in 2000 spacing was standardized to 2 m. Prior to 1997, survey gear was retrieved 1 hour after deployment. A 3 - to 11-hour soak time was implemented in 1997 to match the minimum 3-hour soak time on the federal longline survey and to address concerns that the 1-hour soak time was not sufficient for gear to reach the bottom and be available for fish at certain depths and tidal/current conditions (Cartwright 2000). In addition, herring was replaced with squid as bait in 1997 partially due to the concern that herring disintegrates with longer soak times (Cartwright 2000).

Since 1997, mark-recapture activities have occurred to estimate absolute abundance of sablefish in NSEI. From 1997 to 1999, sablefish were marked during the annual NSEI longline survey; however, tag recovery data indicated tagged fish released using longline gear were avoiding subsequent capture with longline gear (Carlile et al. 2002). In 2000, to avoid this potential bias and more accurately assess abundance, the department began using longlined pots to mark sablefish.

Marking surveys also provide release and recapture locations for tagged sablefish. This data allowed for estimation of migration rates and analysis of movement patterns between internal waters and the Gulf of Alaska, Bering Sea, Aleutian Islands, and British Columbia. The probability of sablefish in Chatham Strait moving to any other area is 10%, and for Clarence Strait, 30% (after one year of occupancy; Hanselman et al. 2014).

The department sets the AHO in NSEI for a given year using the survey and fishery data from previous years, because mark-recapture and fishery age structure data cannot be analyzed until after the NSEI fishery has been prosecuted. Prior to 1997, the department set the AHOs for the sablefish fisheries after the longline surveys were completed, just prior to the opening of the fisheries. Since 2003, AHOs have been set in NSEI by applying a harvest rate to an estimate of biomass that is calculated from mark-recapture and weight-at-age data using a Peterson estimator (Dressel 2009; Seber 1982). Currently, abundance is estimated in the current year and forecasted for the upcoming year and is converted to biomass using weight-at-age data; a $F_{50\%}$ harvest rate is applied to the forecast of biomass. The forecasted exploitable biomass for 2014 was 14,933,685 round pounds of sablefish. An $F_{50\%}$ harvest rate of 6.9% was applied to the forecasted biomass to yield a preliminary ABC of 952,538 round pounds for the 2014 NSEI sablefish fishery. This ABC was decremented 206,764 round pounds to account for testfish harvest, estimated mortality in the halibut fishery, discard mortality in the directed fishery, and mortality in subsistence, personal use and sport fish fisheries, resulting in an AHO of 745,774 round pounds for the 2014 NSEI commercial sablefish fishery.

Application of an age-structured model (ASA) using fishery, survey, and mark-recapture data is being explored to estimate abundance of sablefish in NSEI. A similar model is used by NOAA fisheries for the Bering Sea, Aleutian Islands and Gulf of Alaska sablefish assessment.

Unlike NSEI, the department does not currently estimate the absolute abundance of the SSEI sablefish stock. There appears to be substantial movement of sablefish in and out of the SSEI area, violating the assumption of a closed population; consequently, Peterson mark-recapture estimates of abundance or exploitation rates are not possible for this fishery. Instead, the SSEI sablefish population is managed based on relative abundance trends from survey and fishery CPUE data, as well as with survey and fishery biological data that are used to describe the age and size structure of the population and detect recruitment events.

2011–2014 NSEI AND SSEI SEASONS SUMMARY

In 2014, there were reductions in the AHO in both NSEI and SSEI due to declines in the stocks (Table 12; Table 13). From 2011 to October 2014 5,644,729 round pounds of sablefish were harvested (Table 1). The highest harvest in this reporting period occurred in 2012 with 1,491,360 round pounds and the lowest in 2014 with 1,252,571 round pounds harvested through October 2014; however the fishery is open until November 15 (Table 1). The average ex-vessel price was \$3.81 per round pound in 2014.

NSEI

The 2014 NSEI AHO was 745,774 round pounds, a 26% reduction from 2013. This represents the lowest NSEI fishery quota on record (Table 12); this management action was a result of a decrease in the exploitable biomass (Figure 6), a decrease in the longline survey and fishery CPUE (Figure 7), reduction in weight-at-age in the survey and fishery, and a lack of recruitment in NSEI and surrounding areas in recent years (Hanselman et al. 2013). The annual AHO and EQS values were lower in this reporting period than historically (Table 12). Total permit holders in the fishery decreased to a low of 78 permits in 2013 and 2014 (Table 12). The survey and fishery CPUE increased from 2011 to 2012 and then declined from 2012 to 2013 with a more dramatic decline in survey CPUE (Figure 7). The fishery and survey CPUE for 2014 have not yet been analyzed.

SSEI

The SSEI AHO was reduced by 8% in 2014 to 536,618 round pounds, the lowest SSEI quota on record (Table 13); this management action was performed due to a declining trend in the longline survey CPUE (Figure 8), and record high harvests of immature fish in the survey and fishery. The annual AHOs during this reporting period were lower than those in previous years; however, the annual EQS have been slightly higher overall in this reporting period, 25,360 round pounds in 2012 and 2013 and 23,331 round pounds in 2014, due to the reduction in the number of permits (Table 13). The survey and fishery CPUE declined from 2011 to 2012; the survey CPUE continued to decline in 2013 while the fishery CPUE did not change (Figure 8). The fishery and survey CPUE for 2014 have not yet been analyzed.

Survey CPUE in NSEI and SSEI has historically been higher than fishery CPUE. Unlike the fishery, surveys account for sablefish discards and those fish lost at the roller therefore higher CPUE estimates may result. In addition, commercial CPUE estimates may be lower, because in some trips, fishermen may have targeted both halibut and sablefish.

2015 SEASON OUTLOOK

NSEI

The tagging survey, which serves as the first stage of the annual mark-recapture study, was canceled in 2014 due to a reduction in legislative funding and scheduled maintenance for the department survey vessel. The department did conduct the annual longline survey in 2014, collecting CPUE data and sablefish biological information (age, weight, length, sex and maturity). The department also collected sablefish biological data through port sampling of commercial fishery landings. The 2015 NSEI quota decision will be made based on the evaluation of NSEI fishery and survey CPUE, previous NSEI biomass estimates, and the current year's age, length, sex and maturity data. The department plans to conduct another tagging survey in the summer of 2015.

SSEI

The 2015 AHO will be set in the spring after analyses of fishery and survey CPUE and biological data are completed. The department will continue to closely monitor sablefish recruitment trends, age, length, weight and maturity data, as well as survey and fishery performance in SSEI.

PACIFIC COD

Pacific cod are found from the Yellow Sea in China through the Bering Sea as far north as the Chukchi Sea, and south to Santa Monica Bay, California (Love 1996; Westrheim 1996; Mecklenburg et al. 2002). Pacific cod inhabit the waters of the continental shelf and upper continental slope (Bakkala et al. 1984; Westrheim 1996).

FISHERY DEVELOPMENT AND HISTORY

The catch history of the directed Pacific cod fishery in internal waters of Southeast Alaska is incomplete due to some limitations with landing records for this fishery. Under regulation, Pacific cod sold for bait in the crab fisheries must be reported on fish tickets under a catcher-seller permit. However, the amount of Pacific cod retained for bait use in other fisheries is unknown and compliance with this reporting requirement is assumed to be low due to the small number of vessels that report the use of Pacific cod for bait. In addition, Pacific cod taken from directed and bycatch fisheries may be reported on the same CFEC miscellaneous finfish interim use permit card (M card), so it is difficult to differentiate bycatch of Pacific cod from the landings in the directed fishery. Longline gear is the primary gear used in the directed Pacific cod fishery in Southeast Alaska though jig and pot gear are also legal.

A GHR was implemented in 1994 to establish state management authority of Pacific cod in internal waters. In the absence of state regulations, management of Pacific cod in state waters would be subsumed to the federal government. The GHR was set at 750,000–1,250,000 round pounds to accommodate traditional harvest patterns and allow potential expansion of the fishery if additional harvest was deemed sustainable. The directed fishery for Pacific cod has remained open year-round in state waters since the adoption of the GHR in 1994; however, area closures have been implemented during this time due to concerns of possible localized depletion.

Reported landings of Pacific cod from NSEI and SSEI have varied widely over the past 20 years (Table 14). The increase in catch in the 1990s was due to the development of a food market for Pacific cod. Total annual reported landings of Pacific cod from NSEI and SSEI have ranged from 142,405 round pounds (1985) to 962,434 round pounds (1993) with most of this harvest landed on miscellaneous finfish interim use permits (Table 14). On average, 88% of the Pacific cod landings have come from the directed fishery with a range of 18 to 179 miscellaneous finfish interim use permits landing Pacific cod in the directed fishery from 1985 to 2014 (Table 14).

REGULATIONS

In 2000, the board limited gear for the harvest of Pacific cod to longline, dinglebar troll, hand troll, mechanical jigs, and pot gear. In 2012, the board defined the open fishing period for the Pacific cod fishery as January 1–December 31 preventing the need to open and close the fishery by emergency order.

STOCK ASSESSMENT AND MANAGEMENT

There are no department stock assessment surveys for Pacific cod in internal state waters in Southeast Alaska. Pacific cod are sampled at the dock from landings made from the NSEI directed fishery. Biological data are collected for length, sex, maturity, and otoliths. Aging of Pacific cod is problematic and estimated ages are not yet used for assessing stock condition.

In recent history, the directed Pacific cod harvest has been concentrated within a few specific areas in NSEI. To distribute directed fishery harvest throughout the management area and reduce fishing pressure on potential spawning aggregations, the department has implemented in-season closures in some areas when harvests have reached target levels.

2011–2014 SEASONS SUMMARY

Total Pacific cod landings have fluctuated during this reporting period, but are similar to harvest levels in previous years. The highest harvest in the directed fishery during this period occurred in 2013 with 737,708 round pounds and the lowest was in 2012 with 396,616 round pounds (Table 14). Harvests levels have fluctuated some with the market value for Pacific cod; the price per pound can be quite variable even within a given year, dependent on when and what product is sold. As in the past, the majority of the 2013 harvest (97%) was taken in NSEI.

Directed fishing for Pacific cod was closed in several areas in 2011 (Icy Strait and Port Frederick), 2013 (Frederick Sound, Icy Strait, northern Chatham Strait, Port Frederick, southern Lynn Canal, northern Stephens Passage, and Taku Inlet) and 2014 (southern Lynn Canal and northern Stephens Passage) in order to distribute Pacific cod harvest. Inseason closures were implemented because large portions of the annual GHL had been taken in these areas.

2015 SEASON OUTLOOK

Pacific cod continues to be an important food and bait fish in the EGOA and the fishery provides an opportunity for entry-level participants. If the market value of Pacific cod remains high enough, this fishery may continue to be important in Southeast Alaska.

FLATFISH

Starry flounder (*Platichthys stellatus*) are the primary species targeted in a beam trawl fishery for flatfish in Southeast Alaska. Starry flounder occur in soft-bottom, shallow water estuaries, generally shallower than 55 fathoms, in the North Pacific (Mecklenburg et al. 2002).

FISHERY DEVELOPMENT AND HISTORY

There is relatively limited estuarine habitat in Southeast Alaska where trawl fisheries are likely to target flatfish. A trawl fishery for flatfish was already established in the internal waters of Southeast Alaska by 1960 when landings of flatfish were first documented. Between 1960 and 1965 approximately 40,000 round pounds of flatfish were harvested annually from Port Camden and delivered to the Yukon Fur Farm on Kupreanof Island for use as mink food. Department reporting records show a substantial increase in annual harvest from low levels in the early 1960s to approximately one million round pounds by 1973 with the harvest dropping substantially by 1980. The harvest in these early years came primarily from Port Camden, Level Island, and the Stikine Flats. These fish were primarily delivered out of state, often in chill-vans, which kept the product live. The fishery again escalated from minimal reported landings in the early 1980s to

landings just over 800,000 round pounds in the late 1980s, consisting primarily of starry flounder and some rock sole (*Lepidopsetta* spp). Harvests remained high from 1987 to 1991 and then decreased to less than 10,000 round pounds by 1995 and since that time have remained at 20,000 round pounds or less per season (Table 15). All the flatfish harvested in 1996 and 1997 were processed in Southeast Alaska, a significant change from previous years. Current GHRs are based on the limited amount of flatfish habitat available, lack of flatfish stock status information, and concerns for potentially high bycatch of crab, shrimp, and halibut (Bracken et al. 1991).

REGULATIONS

The trawl fishery for flatfish is limited to 4 areas: the Stikine Flats, Level Island, Port Camden, and Anita Bay; although, Stikine Flats has been closed to directed fishing since 1989. The beam trawl fishery targets pre-spawning aggregations of flatfish; hence, fishing is limited seasonally. Fishing seasons are October 1–April 15 for Anita Bay fisheries and October 1–November 15 and February 15–April 15 for Port Camden and Level Island fisheries. In 1993 the board implemented a 20,000 round pounds weekly trip limit that is intended to prevent overharvest of the small GHRs in this fishery. In 1997, the board failed to adopt a proposal to increase the weekly trip limit to 35,000 round pounds. Legal gear for directed flatfish fishing in Southeast Alaska was limited to beam trawl gear beginning in 2001.

Department-issued permits are required to participate in the directed beam trawl flatfish fishery. The conditions of this permit require the operator to keep a detailed logbook. Open areas, gear restrictions, and reporting requirements are outlined in the individual permits. Permits are issued for 30 days and are renewable at the department’s discretion. The department may also require on-board observer coverage.

STOCK ASSESSMENT AND MANAGEMENT

The department currently has little information about the current condition of the flatfish resource in Southeast Alaska as there are no department stock assessment surveys. In the past, on-board observers have collected information on CPUE and biological characteristics of the stock. Data collected in 1988 on the Stikine Flats indicated that the proportion of mature fish in the area was insufficient to support a directed fishery (Bracken et al. 1991). Consequently, this area was closed to directed fishing in 1989 and has remained closed. The most recent management action for the flatfish fishery occurred in April 1998 when the department closed the Anita Bay area to directed trawl fishing when the area GHL had been met.

2011–2014 SEASONS SUMMARY

Fishing effort in the directed flatfish fishery continued to be low during this reporting period; however, one permit directed fished during the 2013–2014 fishing season. This was the first directed fishing since the 1998–1999 fishing season. Flatfish harvest is reported across years, because the fishing season is from October to April 15. Only one permit fished in 2013–2014; consequently, this information is confidential. In addition, 862 round pounds of flatfish were harvested as bycatch and used as bait during the 2010–2011 seasons.

2015 SEASON OUTLOOK

The department will consider permits as requested with an emphasis on collecting biological data on flatfish as well as associated bycatch information.

OTHER SPECIES

Landings of other groundfish species in NSEI and SSEI continue to be low. The majority of other species not noted above are discarded at-sea and not reported on fish tickets. Primary discards include Pacific sleeper sharks (*Somniosus pacificus*), spiny dogfish (*Squalus suckleyi*)³, spotted ratfish (*Hydrolagus colliei*), skates (Family Rajidae), arrowtooth flounder (*Atheresthes stomias*), hagfish (*Eptatretus deani*), and grenadiers (Family Macrouridae). Skate landings in internal waters of NSEI and SSEI during this reporting period (2011–2014) totaled 98,373 round pounds. Landings fluctuated annually with a low harvest in 2011 of 3,206 round pounds and a high in 2014 of 47,959 round pounds. Skates harvest fluctuates with current market value.

³ Since 2010, spiny dogfish have been identified as *Squalus suckleyi* and separated from the Atlantic species of dogfish *S. acanthias* based on morphology and genetics; however, in regulation they are still identified as *S. acanthias*.

Note: For species with high mortality after capture, fish discarded at-sea were included in the catch estimates for 2010–2014; this includes all *Sebastes* and *Sebastolobus* rockfishes (DSR, PSR, slope, and black rockfishes) and Pacific cod. All other catch numbers reflect landings only.

Table 2.—Groundfish bycatch (round pounds) landed in the Southeast Alaska commercial salmon troll fisheries, 1990 through October 2014. DSR include the demersal shelf rockfish assemblage, PSR includes all pelagic shelf rockfish, and slope rockfish include rockfish (*Sebastes* and *Sebastolobus* spp.) not included in the DSR and PSR assemblages.

^a Delivery code for lingcod was not documented in the troll fishery prior to 2001; consequently, round weights prior to this time should be considered estimates. These weights were calculated by converting landed weights with the standard western cut delivery conversion rate.

Table 3.—Testfish landings (round pounds) and ex-vessel values for Alaska Department of Fish and Game and International Pacific Halibut Commission surveys, by group and year for state-managed species, 1999 through October 2014. DSR include the demersal shelf rockfish assemblage, PSR includes all pelagic shelf rockfish, and slope rockfish include all rockfish (*Sebastes* and *Sebastolobus* spp.) not included in the DSR and PSR assemblages.

Note: Directed fishery permit, Y, was implemented in 1990 for all areas except EYKT which was implemented in 1992. Prior to Y cards, trips with M card were considered DSR target if >40% harvest was DSR.

- ^a DSR assemblage includes: bocaccio, canary, china, copper, quillback, redstripe, rosethorn, silvergray, tiger, yelloweye, and unspecified DSR.
- ^b The number of directed fishery permits could not be determined prior to the directed fishery permit card in 1990.
- ^c DSR assemblage includes: canary, china, copper, quillback, rosethorn, tiger, yelloweye, and unspecified DSR.
- ^d DSR assemblage includes: canary, china, copper, quillback, redbanded, rosethorn, tiger, yelloweye, and unspecified DSR.
