## Symbols and Abbreviations

The following symbols and abbreviations, and others approved for the Système International d'Unités (SI), are used without definition in the following reports by the Divisions of Sport Fish and of Commercial Fisheries: Fishery Manuscripts, Fishery Data Series Reports, Fishery Management Reports, and Special Publications. All others, including deviations from definitions listed below, are noted in the text at first mention, as well as in the titles or footnotes of tables, and in figure or figure captions.

| Weights and measures (metric) General |  |  |  | Mathematics, statistics all standard mathematical signs, symbols and abbreviations |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

February 2019

The Fishery Manuscript Series was established in 1987 by the Division of Sport Fish for the publication of technically-oriented results of several years' work undertaken on a project to address common objectives, provide an overview of work undertaken through multiple projects to address specific research or management goal(s), or new and/or highly technical methods, and became a joint divisional series in 2004 with the Division of Commercial Fisheries. Fishery Manuscripts are intended for fishery and other technical professionals. Fishery Manuscripts are available through the Alaska State Library and on the Internet: http://www.adfg.alaska.gov/sf/publications/ This publication has undergone editorial and peer review.

#### Abstract

In February 2018, an interdivisional team of staff from the Alaska Department of Fish and Game reviewed existing Pacific salmon Oncorhynchus spp. escapement goals in the Chignik Management Area (CMA). The 6 CMA salmon escapement goals were last reviewed in 2015. In 2018, the team reviewed recent data to determine whether substantial new information existed to warrant analyzing and updating the goals. The team determined Chignik Chinook salmon warranted further review. No goal revisions were recommended by the review team. No goals were eliminated and none were added for systems currently without escapement goals.

Key words: Pacific salmon, Oncorhynchus, escapement goal, Chignik, Chignik Management Area, Chignik Lake, Black Lake, stock status

## INTRODUCTION

This report documents the 2018 review of salmon escapement goals in the Chignik Management Area (CMA) based on the Alaska Board of Fisheries’ (BOF) Policy for the Management of Sustainable Salmon Fisheries (5 AAC 39.222) and the Policy for Statewide Salmon Escapement Goals (5 AAC 39.223). Recommendations from this review are made to the directors of the divisions of Commercial Fisheries and Sport Fish of the Alaska Department of Fish and Game (ADF\&G), and are intended to take effect for salmon stocks returning in 2019. Salmon escapement goals in the CMA were last reviewed in 2015 (Schaberg et al. 2015).
Three important terms defined in the Policy for the Management of Sustainable Salmon Fisheries are listed below:

- biological escapement goal (BEG): the escapement that provides the greatest potential for maximum sustained yield (MSY);
- sustainable escapement goal (SEG): a level of escapement, indicated by an index or an escapement estimate, that is known to provide for sustained yield over a 5 to 10 year period, used in situations where a BEG cannot be estimated or managed for; and
- inriver run goal (IRRG): a specific management objective for salmon stocks that are subject to harvest upstream of the point where escapement is estimated; the inriver run goal will be set in regulation by the BOF and is comprised of the SEG, BEG, or optimal escapement goal, plus specific allocations to inriver fisheries.

Since the inception of the Policy for Statewide Salmon Escapement Goals in 2001, escapement goals for the CMA have been reviewed 5 times (Witteveen et al. 2005, Witteveen et al. 2007, Nemeth et al. 2010, Sagalkin et al. 2013, Schaberg et al. 2015 ). These reviews correspond with area BOF meetings, which have historically been on a 3-year cycle; however, the CMA cycle was altered in 2014 and the review in 2015 only reflected 2 additional years of data (2013-2014). This review will incorporate the recent 3 years of escapement data, restoring the 3-year cycle.
In February 2018, the Salmon Escapement Goal Interdivisional Review Team (hereafter referred to as the team) was formed to review the existing CMA salmon escapement goals and recent escapements for stocks without escapement goals. The team included staff from the Division of Commercial Fisheries (CF) and the Division of Sport Fish (SF): Kevin Schaberg (CF), Tim McKinley (SF), Nicholas Sagalkin (CF), Heather Finkle (CF), M. Birch Foster (CF), Michelle Wattum (CF), Jeff Wadle (CF), Dawn Wilburn (CF), Ross Renick (CF), Bob Murphy (CF), Lisa Fox (CF), Cassandra Whiteside (CF), Lucas Stumpf (CF), Bill Templin (CF), Andrew Munro (CF), Jim Hasbrouck (SF), Tom Vania (SF), Dan Bosch (SF), Mark Witteveen (SF), Adam St. Saviour (SF), David Evans (SF), and Tyler Polum (SF).

For this review, the team 1) reviewed recent escapements to all stocks with escapement goals; 2) determined the appropriate goal type (BEG or SEG) for each CMA salmon stock with an existing goal, based on the quality and quantity of available data; 3) determined the most appropriate methods to evaluate the escapement goal ranges; 4) estimated the escapement goal for each stock and compared these estimates with the current goal; 5) determined if a goal could be developed for any stocks or stock-aggregates that currently have no goal; and 6) developed recommendations for each goal evaluated to present to the directors of the divisions of Commercial Fisheries and Sport Fish for approval.

## Management Area

The CMA comprises all coastal waters and inland drainages on the south side of the Alaska Peninsula, bounded by a line extending $135^{\circ}$ southeast for 3 miles from a point near Kilokak Rocks ( $57^{\circ} 10.34^{\prime} \mathrm{N}$ lat, $156^{\circ} 20.22^{\prime} \mathrm{W}$ long) then due south to a line extending $135^{\circ}$ southeast for 3 miles from Kupreanof Point at $55^{\circ} 33.98^{\prime} \mathrm{N}$ lat, $159^{\circ} 35.88^{\prime} \mathrm{W}$ long (Figure 1). The area is divided into 5 commercial fishing districts: Eastern, Central, Chignik Bay, Western, and Perryville districts. These districts are further divided into 14 sections and 38 statistical reporting areas.

The Chignik River is the major watershed in the CMA and consists of 2 interconnecting lakes (Black and Chignik lakes) with a single outlet river (the Chignik River) that empties into the estuary of Chignik Lagoon (Figure 2). All 5 species of Pacific salmon Oncorhynchus spp. return to the Chignik River; sockeye salmon O. nerka returns consist of an early run and a late run, and Chinook salmon O. tshawytscha are only monitored in the river. Pink O. gorbuscha, chum $O$. keta, and coho $O$. kisutch salmon also return to other streams throughout the CMA.

## BACKGROUND

One Chinook salmon stock in the CMA has an established BEG and is located in the Chignik River. This goal was reviewed in 2013 and was left unchanged. Chinook salmon escapement is enumerated through the Chignik River weir. Recent reductions in age samples of the escapement have likely affected the overall age composition estimate. Harvest occurs during directed sport and subsistence fisheries and incidentally in commercial fisheries targeting sockeye, pink, and chum salmon.

Two sockeye salmon stocks in the CMA have established escapement goals. Both of these stocks return to the Chignik River watershed (Figure 2). The majority of the early run (Black Lake stock) enters the watershed from June to July and spawns in Black Lake and its tributaries (Pappas et al. 2003). The majority of the late run (Chignik Lake stock) enters the watershed in July and August, and typically spawns in Chignik Lake tributaries and Chignik Lake shoal areas (Pappas et al. 2003). Although the peak periods of passage for each stock are usually a month apart, there is a period of overlap when both stocks are entering the watershed.

Sockeye salmon bound for Black and Chignik lakes are harvested primarily in the commercial and subsistence fisheries. Escapement of both stocks is enumerated through the use of a weir outfitted with a video camera system as they transit Chignik River. In order to achieve escapement goals for the early and late runs simultaneously, inseason estimates of the numbers of each stock in the daily escapement are required. These estimates have been determined using various methods over time. Prior to 1980, time-of-entry relationships based on tagging studies and age groups were employed to divide the catch and escapement between the 2 runs (Dahlberg
1968). From 1980 to 2003, with the exception of 1982, stock separation was accomplished using scale pattern analysis (Witteveen and Botz 2004). Beginning in 2004, an estimate of the earlyrun escapement was based on weir counts through July 4. After July 4, the fish that passed upstream through the weir were assumed to be late-run fish. ${ }^{1}$ This method was determined not to be significantly different ( $\mathrm{P}>0.05$ ) than the scale pattern analysis method in estimating recruitment. Beginning in 2014, genetics were used to separate the early- and late-run stocks. In comparison to the transition date of July 4, logistic run timing during the overlap period suggest that utilizing inseason genetic information results in more biologically sound escapement-based management (Anderson et al. 2013; Foster 2013). During 2014 through 2017 the inseason use of genetics to estimate early- and late-run stock proportions demonstrated the variable timing of entry into Chignik River and presented the department with the challenge of applying these proportions for management purposes. The genetic based inseason estimates did not provide effective inseason adaptive management tools because of the time sensitive nature of fisheries management and the lag time of genetics results. In 2018, the central tendency of the genetic based logistic model was used to apportion escapement between the two runs inseason; however, genetic samples collected at the weir were used to inform postseason run reconstruction. ${ }^{2}$

Due to the late run timing of coho salmon returns to the CMA, there are no established coho salmon escapement goals. The vast majority of coho salmon escapement occurs after the Chignik River weir is pulled for the season and inclement fall weather precludes reliable aerial surveys for estimating escapement.

Pink salmon in the CMA are managed to achieve escapement goals based on the aggregates of index streams (Table 1; Figure 1). Separate areawide BEGs were established for odd and even years during the 2004 review (Witteveen et al. 2005) and amended to SEGs during the 2007 review (Witteveen et al. 2007). These aggregate goals were revised in 2015, and comprise the respective sums of aerial survey escapement estimates for 8 individual index streams (Schaberg et al. 2015).
Chum salmon in the CMA are managed to achieve an escapement goal based on aggregates of index streams, similar to pink salmon (Table 1; Figure 1). This aggregate SEG was revised in 2015, and comprises the respective sums of aerial survey escapement estimates for 6 individual index streams (Schaberg et al. 2015).

## METHODS

During the review process, one Chinook, two sockeye, one chum, and two pink salmon escapement goals were evaluated (Table 1). We conducted our review similarly to the 2015 review (Schaberg et al. 2015), primarily examining recent (2015-2017) data and updating previous analyses. A formal meeting, via teleconference, to discuss and develop recommendations was held on February 1, 2018. The team also communicated on a regular basis by telephone and email.

Available escapement, harvest, and age data associated with each stock or combination of stocks to be examined were compiled from research reports, management reports, and unpublished

[^0]historical databases. Limnological and spawning habitat data were compiled for each system when available. The team evaluated the type, quality, and amount of data for each stock according to criteria described in Clark et al. (2014; Table 2). This evaluation was used to assist in determining the appropriate type of escapement goal to apply to each stock, as defined in the Policy for the Management of Sustainable Salmon Fisheries and the Policy for Statewide Salmon Escapement Goals.

## Escapement Goal Determination

## Biological Escapement Goal

In Alaska, most salmon BEGs are developed using Ricker (1954) spawner-recruit models (Munro 2018). BEG ranges, as defined in the Policy for the management of sustainable fisheries, are estimates of the number of spawners that provide the greatest potential for maximum sustained yield, abbreviated as $\mathrm{S}_{\text {msy }}$. Only the Chignik River sockeye and Chinook salmon stocks have data sufficient for this type of analysis, and of these stocks, only the Chinook salmon stock was identified for further review this cycle.

## Sustainable Escapement Goal

Sustainable escapement goals (SEGs) for Area M salmon stocks were determined using the " 4 tier Percentile Approach" of Bue and Hasbrouck (Unpublished) for goals implemented prior to 2014 and the Clark et al. (2014) "3-tier Percentile Approach" for goals reevaluated and implemented after 2014. The 3-tier Percentile Approach is based on the principle that escapements of a stock within some range of percentiles observed over the time series of escapements and associated harvest from fishing represents a proxy for maintaining escapements within a range that encompasses $\mathrm{S}_{\text {MSY }}$ (Clark et al. 2014).

The 3-tier Percentile Approach takes into account the measurement error of the data collection method (i.e., weirs and towers have lower measurement error than aerial or foot surveys), contrast of the escapement data (i.e., the ratio of highest observed escapement to the lowest observed escapement), and the average harvest rate of the stock. Based on these criteria Clark et al. (2014) recommended the following tiers to set an SEG range.

| Tier | Escapement <br> contrast | $>8$ | High (aerial and foot <br> surveys) | Low to moderate <br> $(<.40)$ |
| :---: | :---: | :---: | :--- | :---: |
| 1 | $>8$ | Low (weirs and <br> towers) | Low to moderate <br> $(<.40)$ | 15th to 65th Percentile |

## Chinook Salmon

## Escapement Goal Background and Previous Review

The Chignik River has the only Chinook salmon escapement goal established in the CMA (Table 1; Appendix A1). Chinook salmon escapement to the Chignik River is estimated using a weir outfitted with a video camera (Anderson et al. 2013). The escapement goal was first established in 1992 (1,750 to 3,000 fish; Nelson and Lloyd 2001) and changed to a BEG (1,450
to 2,700 fish) using a spawner-recruit model in 1994 (Nelson and Lloyd 2001). The BEG was changed to an SEG for 1 year in 2001 (Nelson and Lloyd 2001), then revised back to a BEG of 1,300 to 2,700 fish in 2002 (Witteveen et al. 2005). Since 2002 the goal has remained unchanged (Appendix A1: Witteveen et al. 2005; Witteveen et al. 2007; Nemeth et al. 2010; Sagalkin et al. 2013; Schaberg et al. 2015).

## Stock Status

Since the establishment of the current BEG of 1,300 to 2,700 fish in 2002, escapements of Chignik River Chinook salmon have been within or above the escapement goal range in all years except 2013 and 2017 (Appendices A2 and A4).

## 2018 Review

With 14 more years of spawner-recruit data since the last analysis (Appendix A3), an updated analysis and review of the Chignik River Chinook salmon run was warranted. Total run was estimated from weir estimates (1978-2017), commercial harvests from Chignik Lagoon (19782017; statistical area 271-10) were obtained from fish tickets, subsistence harvests (1978-2017) were obtained from returned permits, and sport harvest above and below the weir (2005-2016) were obtained from guide log books. Sport harvest prior to 2005 was modelled as a function of average exploitation rate during 2005-2016 and total run. Age composition data (1993-2001 and 2013-2017) were obtained primarily by sampling the fish, but the commercial and sport fisheries were also sampled in some years. These data were assumed to represent the age composition of the run in each calendar year. Escapement, harvest, and age data were combined to reconstruct the Chignik River Chinook salmon run and create a brood table.
A Bayesian age-structured state-space model was fitted to the Chignik River Chinook salmon total run, escapement, and age composition data. The model used the methods described in Fleischman et al. (2013) and was set up with a Ricker spawner-recruit relationship, autoregressive lag-1 productivity and a Dirichlet age-at-maturity schedule. A trending age-atmaturity schedule component (A. Reimer, Sport Fish Biometrician ADF\&G, personal communication) was also examined but had little influence on results and was not considered further.

The model was fitted in R (R Core Team, 2017) using multi-chain Monte Carlo (MCMC) techniques in the package rjags (Plummer 2016). MCMC samples were drawn from the joint posterior probability distribution of all unknowns in the model. For each of 2 Markov chains initialized, a 300,000-sample burn-in was discarded, after which each chain ran for an additional 100,000 iterations. After thinning by a factor of 10 , a total of 20,000 samples were used to estimate the marginal posterior statistics. Gelman-Rubin convergence diagnostics (Brooks and Gelman 1998) along with visual inspections of trace plots of the various posterior statistics were used to assess convergence of the chains.
Medians of important spawner recruit statistics (e.g., $\mathrm{S}_{\text {msy }}, \mathrm{S}_{\text {max }}, \mathrm{S}_{\text {eq }}$, Ricker alpha and beta parameters) were estimated. Credibility interval estimates were obtained for each reported statistic from the percentiles of the posterior distribution. Sustainable yield curves (Fleischman et al. 2013) and the fitted Ricker model were also plotted.

## Sockeye Salmon

## Escapement Goal Background and Previous Review

Chignik River sockeye salmon are the only sockeye salmon stocks in the CMA with escapement goals (Table 1). Sockeye salmon also return to several smaller stream systems in the CMA, but due to small run sizes and limited effort, escapement goals for these streams have not been established (Witteveen et. al. 2007). Although the peak periods of passage for Chignik River early- and late-run stocks are usually 1 month apart, the 2 runs overlap in late June and July (Templin et al. 1999). Escapement estimates for both runs are based on weir estimates with the addition of post-weir estimates for the late run that were modeled after the weir was removed in early September (Anderson et al. 2013).

Escapement goals for Chignik River sockeye salmon were originally established in 1968, and set at 350,000 to 400,000 fish for the early run and 200,000 to 250,000 fish for the late run (Dahlberg 1968). In 1998, the BOF established a September 1-15 management objective of 25,000 fish, supplemental to the lower bound of the late-run goal, to accommodate subsistence fishers upstream of the Chignik weir. In 2004, the numerical ranges of the goals were left in place, but the goals were reclassified as SEGs because scientifically-defensible estimates of $\mathrm{S}_{\text {MSY }}$ were not possible. Also in 2004, the BOF established an August management objective of 25,000 fish (in addition to the existing September management objective) to further provide subsistence opportunities upstream of the weir. In 2007, the late-run SEG was changed to 200,000 to 400,000 fish, and the two 25,000-fish management objectives were reclassified as inriver run goals (IRRG; Witteveen et al. 2007). Actual timing of adoption of the inriver goal is unclear from other documents as it was initially just a management objective that was expanded over 2 cycles (1989 and 2004), but was adopted as a formal inriver goal in 2007. In 2013 the early-run goal was changed from an SEG to a BEG and the range was increased to 350,000 to 450,000 fish and the IRRG was officially put into regulation (Sagalkin et al. 2013). In 2015 no changes were made to the Chignik sockeye salmon escapement goals (Schaberg et al. 2015); however, the BOF increased the inriver goal by 25,000 fish in September. The inriver run goals are currently 25,000 fish in August and 50,000 fish in September, for a total of 75,000 fish above lower bound of the late-run SEG.

## Stock Status

The current Chignik River early-run escapement goal range ( 350,000 to 450,000 ) was established in 2013 and classified as a BEG. In the last 10 years, early-run escapements have been within or above ( 4 times) the goal every year. The late-run escapements have met the current SEG range (200,000 to 400,000), or have been above (1 time) the goal every year since implementation in 2008 (Appendix B). The IRRGs have not been met every year due to the time specific requirements, and lack of weir operation throughout the time IRRGs are in effect. The August component has been achieved in 10 of the last 12 years (not in 2011 or 2014) and the September IRRG has not been met since the escapement goal was updated in 2016 and was only achieved in 3 of the 9 years from 2007-2015 when it was from September 1-15.

## 2018 Review

Escapements in 2015-2017 exceeded or were within the range of the early-run BEG and the laterun SEG (Table 1; Appendices B2-B4). There was no compelling new information since the last review, and the team agreed that no further analysis was necessary in 2018.

## Pink Salmon

## Escapement Goal Background and Previous Review

Pink salmon escapement goals in the CMA were originally established in 1999, with separate goals for each of the five commercial salmon fishing districts (Figure 1, Witteveen et al. 2005). Annual escapement estimates are based on aerial surveys of fish in as many as 49 streams throughout the area. Escapements from 1984 to 2004 were estimated using area-under-the-curve methodology assuming a 15-day stream life (Johnson and Barrett 1988) and were referred to as estimated total escapement. During the 2004 escapement goal review, an investigation of the peak escapement counts versus the estimated total escapement revealed several inconsistencies in the database. Because the calculation inconsistencies resulted in unreliable estimates, the review in 2004 used peak escapement counts (Witteveen et al. 2005). Subsequently, fisheries management has relied on peak escapement counts to measure achievement of escapement goals, and all escapement goal reviews since 2004 have also used peak escapement counts.

Also in 2004, the goals for individual districts were removed and replaced with a single aggregate goal for the entire CMA developed using a stock-recruit analysis of peak aerial surveys for 49 streams throughout the 5 commercial fishing districts (Table 1; Figure 1). This aggregate goal was established as a BEG, with separate goal ranges for odd- and even-year returns of pink salmon (Witteveen et al. 2005). In 2007, the goals were reanalyzed using the yield analysis methods of Hilborn and Walters (1992). Due to lack of precision in aerial survey data, the goals were increased and reclassified as SEGs of 200,000 to 600,000 fish during even years and 500,000 to 800,000 fish for odd years (Witteveen et al. 2007). In the 2012 review, the team determined that the additional stock assessment data would not substantially affect the results of the previous escapement goal analyses. Thus there was consensus to not reevaluate the goals in 2012, and there was no change to the even- and odd-year Chignik pink salmon SEGs (Witteveen et al. 2009; Sagalkin et al. 2013). During the 2015 review, a restrictive set of criteria were applied to the peak aerial survey counts to allow for more consistency in the aggregate index based escapement goals. This resulted in a reduction of index streams from 49 to 8 (Schaberg et al. 2015). This also resulted in a reduction to the number of fish incorporated in the new indices, to which the 3-tier Percentile Approach (Clark et al. 2014) was applied. The aggregate pink salmon SEG for odd years (260,000 to 450,000 fish), and for even years (170,000 to 280,000 fish) were adopted starting in the 2016 season (Appendix C1; Schaberg et al. 2015).

## Stock Status

Even-year pink salmon escapements from 1980-2004 were consistently high, averaging around 315,000 pink salmon annually. Even-year pink salmon aggregate escapements were within or exceeded the escapement goal range following the inception of the escapement goal in 2008 (Schaberg et al. 2015), although recent years of even-year returns have been among the lowest since 1980. The adoption of the revised SEG in 2016 has only been evaluated with one even year, and the 2016 escapement did not achieve the SEG (Table 1; Appendices C2 and C3).

Odd-year pink salmon escapement estimates were low in the early 1980s, with larger escapement observed beginning in 1989. Odd-year pink salmon escapement estimates were especially high between 1995 and 2007, averaging over 1 million pink salmon each year. With the inception of the SEG in 2008, odd-year escapement was above the upper bound of the current escapement goal range (Schaberg et al. 2015). The revised odd-year SEG, adopted in 2016, was exceeded in 2017 (Table 1; Appendices C2 and C3).

## 2018 Review

Stock-specific harvest estimates for Chignik pink salmon are not available. In 2018, recent escapement data (Appendices C2-C3) were examined to determine if a change in the escapement goal was justified. The team determined that this stock did not warrant further review.

## CHUM SALMON

## Escapement Goal Background and Previous Review

Chum salmon escapement goals in the CMA were originally established in 1999, with separate goals for each of the 5 commercial salmon fishing districts (Nelson and Lloyd 2001). Escapements from 1984 to 2004 were estimated using area-under-the-curve methodology assuming a 15-day stream life (Johnson and Barrett 1988) and were referred to as estimated total escapement. During the 2004 escapement goal review, an investigation of the peak escapement counts versus the estimated total escapement revealed several inconsistencies in the database. Because the calculation inconsistencies resulted in unreliable estimates, the review in 2004 used peak escapement counts (Witteveen et al. 2005). Subsequently, fisheries management has relied on peak escapement counts to measure achievement of escapement goals, and all escapement goal reviews since 2004 have also used peak escapement counts.

Chum salmon escapement goals were revised in 2004 to represent an aggregate goal for the entire CMA. This goal was developed using results of aerial surveys for 49 streams throughout the 5 commercial fishing districts (Figure 1). This single aggregate goal in 2004 was developed using the 4-tier Percentile Approach and risk analysis and was reclassified as a lower bound SEG (Witteveen et al. 2005). In 2007, the aggregate lower bound SEG was reanalyzed using a risk analysis (Bernard et al. 2009) and raised to 57,400 fish (Witteveen et al. 2007). In 2010 and 2013, the most recent escapements were reviewed and no change was recommended to the goal. During the 2015 review, a restrictive set of criteria were applied to the peak aerial survey counts to allow for more consistency in the aggregate index based escapement goals. This resulted in a reduction of index streams from 49 to 6 (Schaberg et al. 2015). This also resulted in a reduction to the number of fish incorporated in the new indices to which the 3-tier Percentile Approach (Clark et al. 2014) was applied. The aggregate chum salmon SEG range (45,000 to 110,000 fish) was adopted starting in the 2016 season (Table 1; Appendix D1; Schaberg et al. 2015).

## Stock Status

Chum salmon aggregate escapements were above the lower-bound SEG from 2008-2015. With the revised SEG from 2016 and subsequent reduction in the number of streams included in the index, the chum salmon escapement in the CMA was within the SEG range in 2016 and 2017 (Table 1; Appendix D).

## 2018 Review

Stock-specific harvest estimates for Chignik chum salmon were not available. Recent escapement data (Appendices D2-D4) were examined to determine if a change in the escapement goal was justified. The team determined that this stock did not warrant further review.

## RESULTS

## CHINOOK SALMON

## Escapement Goal Recommendation

The median of the posterior distribution of estimates of $S_{\text {mSY }}$ for Chignik River Chinook salmon is 1,993 ( $95 \%$ credibility interval of 1,373 to 4,146 fish; Appendix A5). A return vs. spawner plot, along with the fitted model and credibility intervals, is presented in Appendix A6. The analysis suggests there is substantial positive autocorrelation ( $\phi=0.6$; Appendix A5). No major problems were encountered in assessment of convergence of the MCMC chains. The yield curves (Appendix A7) provide no compelling evidence to change the current goal of 1,300-2,700.

## SUMMARY OF RECOMMENDATIONS

The team concluded that the 3 additional years of data since the 2015 review would not affect the existing escapement goals for the Chignik River early- and late-run sockeye, or chum and pink salmon stocks. There are no coho salmon escapement goals in the CMA because harvests are generally incidental to the sockeye salmon fishery and because the late run timing of coho salmon prevents reliable estimates of escapement. The team elected to further analyze the Chinook salmon escapement goal.
The final recommendation of the 2018 review team was to maintain the CMA Chinook salmon BEG of 1,300 to 2,700 fish.

| Pink salmon | CMA aggregate odd years | PAS | SEG | 260,000-450,000 | 404,000 |  | 586,000 | No change |
|  | CMA aggregate even years | PAS | SEG | 170,000-280,000 |  | 68,100 |  | No change |
| Chum salmon | CMA aggregate | PAS | SEG | 45,000-110,000 | 123,400 | 69,900 | 96,900 | No change |

a PAS = Peak Aerial Survey, WC= Weir Count.
b This escapement reflects the weir count, discounting sport harvest above the weir.
c This lower bound does not include the inriver run goal of 75,000 fish.

Table 2.-General criteria used to assess quality of data in estimating CMA salmon escapement goals.

| Data quality | Criteria |
| :--- | :--- |
| Excellent | Escapement, harvest, and age all estimated with relatively good accuracy and precision (i.e., <br> escapement estimated by a weir or hydroacoustics, harvest estimated by Statewide Harvest <br> Survey or fish tickets with harvest apportioned to stock of origin); escapement and return <br> estimates can be derived for a sufficient time series to construct a brood table and estimate <br> Smsy. |
| Good | Escapement, harvest, and age estimated with reasonably good accuracy and/or precision <br> (i.e., escapement estimated by capture-recapture experiment or multiple foot/aerial surveys; <br> harvest estimated by Statewide Harvest Survey or fish tickets); no age data or data of <br> questionable accuracy and/or precision; data may allow construction of brood table; data <br> time series relatively short to accurately estimate Smsy. |
| Fair | Escapement estimated or indexed and harvest estimated with reasonably good accuracy but <br> precision lacking for one if not both; no age data; data insufficient to estimate total return <br> and construct brood table. |
| Poor | Escapement indexed (i.e., single foot/aerial survey) such that the index provides only a fairly <br> reliable measure of escapement; no harvest and age data. |

a Commercial harvest is the commercial harvest of Chinook salmon from the Chignik Lagoon statistical area (271-10).
This does not include personal use or test fishery harvest.
b Subsistence harvest is from Chignik Lagoon as reported on subsistence permit reports.
c Sport harvest in 1988 and 1989 was estimated from an onsite creel survey (Schwarz 1990). Recreational harvest in the remaining years is the average of 1988 and 1989.
d Beginning in 2005, sport fish harvest is estimated through guide logbooks.
e Escapement is weir count minus sport harvest.
f Data not available at the time of publication.

Appendix A3.-Chignik River Chinook salmon brood table by total age, 1978 to 2017.

System: Chignik River
Species: Chinook salmon

| Brood |  | Return by total age ${ }^{\text {a }}$ |  |  |  |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | Escapement | 3 | 4 | 5 | 6 | 7 | Total | Return | | Return/ |
| ---: |
| Spawner |

a Age composition used to estimate return at age from 1980 to 1992 uses the average age composition from 1993 to 2000. Adequate samples from 1993 to 2005, 2013, and 2014 were used to estimate the age composition from 2006 to 2012 when data was not collected.

Appendix A4.-Annual escapements and escapement goals for Chignik River Chinook salmon, 1978 to present, with current and historical SEGs (dotted lines) and BEGs (solid lines).

Appendix A6.-Chignik River Chinook salmon fitted Ricker relationship, R-S pairs and R = S; error bars are $90 \%$ credibility intervals.

System: Chignik River
Species: Chinook salmon

Appendix A7.-Chignik River Chinook salmon probability that sustained yield (SY) is greater than X\% of maximum sustained yield (MSY).

System: Chignik River
Species: Chinook salmon

# APPENDIX B. SUPPORTING INFORMATION FOR CHIGNIK RIVER WATERSHED SOCKEYE SALMON ESCAPEMENT GOALS 

Appendix B1.-Description of stocks and escapement goals for Chignik River watershed sockeye salmon.

System: Chignik River
Species: Sockeye salmon

| Regulatory area: | Chignik Management Area |
| :---: | :---: |
| Management division: | Commercial Fisheries |
| Primary fishery: | Commercial purse seine |
| Current escapement goal: | Early-Run BEG: 350,000 to 450,000 fish (2014) |
|  | Late-run SEG: 200,000 to 400,000 fish (2008) |
| Recommended escapement goal: | Early-Run BEG: No change |
|  | Late-run SEG: No change |
| Optimal escapement goal: Inriver run goal: | None |
|  | 1998: 25,000 management objective for September 1-15 in addition to lower bound; 2004: In addition to the existing 25,000 September objective a 25,000 objective was added for August. |
|  | 2008: The two management objectives were reclassified as inriver run goals but not added into regulation. |
|  | 2013: IRRG added into regulation. |
|  | 2015: An additional 25,000 sockeye salmon were added to the September inriver run goal, for a total of 50,000 fish in September. The August inriver run goal remained at 25,000 sockeye salmon. |
| Action points: | None |
| Escapement enumeration: | Weir 1922, 1923, 1925 to 1930, 1932, 1933, 1935 to 1937, 1939, 1949 to 1950, 1952 to present; run reconstruction in remaining years through professional observation and cannery records. |
| Data summary |  |
| Data quality: | Fair |
| Data type: | Weir counts intermittently for 16 of the 29 years between 1922 and 1951 and from 1952 to present. Escapement age data available from 1955 to 1960, 1962 to 1969, and 1980 to 2009. Stock-specific harvest information was available for 1962 to 1969 and 1980 to 2009. Smolt outmigration data from 1994 to present. Limnology data from 2000 to present. |
| Contrast: | 1922 to 2017: 514.2 (early run) |
|  | 1978 to 2017: 2.2 (early run) |
|  | 1922 to 2017: 11.6 (late run) |
|  | 1978 to 2017: 2.8 (late run) |
| Methodology: | Ricker stock-recruit model, yield analysis, euphotic volume model, zooplankton biomass model, percentile approach |
| Autocorrelation: | None detected |

Appendix B2.-Annual escapements for early- and late-run Chignik River sockeye salmon, 1922 to 2017, with current and historical SEGs (dotted lines) and BEGs (solid lines).

System: Chignik River
Species: Sockeye salmon

# APPENDIX C. SUPPORTING INFORMATION FOR CHIGNIK MANAGEMENT AREA PINK SALMON ESCAPEMENT GOALS 

Appendix C1.-Description of stock and escapement goal for Chignik pink salmon.
$\begin{array}{ll}\text { System: } & \text { Entire CMA } \\ \text { Species: } & \text { Pink salmon }\end{array}$

| Regulatory area | Chignik Management Area |
| :---: | :---: |
| Management division: | Commercial Fisheries |
| Primary fishery: | Commercial purse seine |
| Current escapement goal: | SEG (even years): 170,000 to 280,000 (2016) |
|  | SEG (odd years): 260,000 to 450,000 (2016) |
| Recommended escapement goal: | SEG (even years): No change |
|  | SEG (odd years): No change |
| Optimal escapement goal: | None |
| Inriver goal: | None |
| Action points: | None |
| Escapement enumeration: | Aerial survey, 1980 to present |
| Data summary |  |
| Data quality: | Poor |
| Data type: | Fixed-wing aerial surveys from 1980 to present. Data used in analysis represents indicator streams and years from each district with a complete survey dataset from 1980 to present. No stock-specific harvest information is available. |
| Data Contrast: | Even years: 5.8; Odd Years: 5.5 |
| Methodology: | Percentile |
| Criteria for SEG: | Moderate contrast, low exploitation |
| Percentiles: | 20th to 60th |
| Comments: | Data from 1980 to 2017 were used from systems with complete survey histories, in years with a majority of systems surveyed, and indicator streams selected based on contribution to district and area-wide escapement estimates. Eight area-wide systems were chosen to represent an indexed escapement goal: Aniakchak River 272-605, Main Creek 272-702, Chiginagak Bay East 272-905, Kumlium Creek 272-501, North Fork River 272-514, Ivan River 273-722, Ivanof River 275-406, Humpback Creek 275-502. |

Appendix C2.-Chignik pink salmon peak aerial survey counts (PAS), in selected indicator streams 1980-2017.

System: Chignik Management Area
Species: Pink salmon

Note: Systems not successfully surveyed in a survey year are indicated with "-". If 1 or more systems in a survey year were not successfully surveyed, the Index Total was not calculated and is noted as "-".

# APPENDIX D. SUPPORTING INFORMATION FOR THE CHIGNIK MANAGEMENT AREA CHUM SALMON ESCAPEMENT GOAL 

Appendix D1.-Description of stocks and escapement goal for chum salmon in the entire CMA.
System: Entire CMA
Species: Chum salmon

| Regulatory area | Chignik Management Area |
| :---: | :---: |
| Management division: | Commercial Fisheries |
| Primary fishery: | Commercial purse seine |
| Current escapement goal: | SEG: 45,000 to 110,000 (2016) |
| Recommended escapement goal: | No change |
| Optimal escapement goal: | None |
| Inriver goal: | None |
| Action points: | None |
| Escapement enumeration: | Aerial survey, 1981 to present |
| Data summary: |  |
| Data quality: | Poor |
| Data type: | Fixed-wing aerial surveys from 1981 to present. Data used in analysis represents indicator streams and years from each district with a complete survey dataset from 1981 to present. No stockspecific harvest information is available. |
| Contrast: | 10.1 |
| Methodology: | 3-tier Percentile Approach |
| Criteria for SEG: | High contrast, low exploitation |
| Percentiles: | 20th to 60th |
| Comments: | Data from 1981 to 2017 were used from systems with complete survey histories, in years with a majority of systems surveyed, and indicator streams selected based on contribution to district and areawide escapement estimates. Six area-wide systems were chosen to represent an indexed escapement goal; Aniakchak River 272-605, Small Nakililok River 272-804, Chiginagak River 272-903a; Central District: North Fork River 272-514; Portage Creek 273-842; Ivanof River 275-406. |

Appendix D2.-Chignik chum salmon peak aerial survey counts (PAS), in selected indicator streams 1981-2017.

System: Chignik Management Area
Species: Chum salmon

| Year | Small |  |  | North |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Nakalilok River | Aniakchak River | Chiginangak River | Fork River | Portage Creek | Ivanof River | Total Index |
| 1981 | 5,500 | 20,000 | 16,000 | 15,000 | 16,800 | 9,000 | 82,300 |
