Ms. Kaja Brix
Assistant Regional Administrator
Protected Resources Division
Alaska Region
National Marine Fisheries Service
P. O. Box 21668
Juneau, Alaska 99802

ATTN: Ellen Sebastian
SUBJECT: Cook Inlet Beluga Whale PR

Dear Ms. Brix:

The State of Alaska provides the enclosed comments on the "*Proposed Endangered Status for the Cook Inlet Beluga Whale*," published April 20, 2007 (72 FR 76, 19854). The comments include information and analyses of factors that National Marine Fisheries Service (Service) did not consider in reaching its conclusion: "*the Cook Inlet beluga whale constitutes a distinct population segment (DPS) that is in danger of extinction throughout its range.*"

The state's comments provide information relevant to a listing under the Endangered Species Act (ESA), including current population status, biological and other information regarding threats to the species, and effectiveness of ongoing and planned conservation efforts. That information reveals that a slow recovery should have been expected and the population is now beginning to increase. Examples of significant economic impacts of designation of critical habitat are also provided. The state identifies areas within Cook Inlet that should be identified as an 'essential feature' and granted exclusion protection.

The state comments enclosed clearly demonstrate that the Cook Inlet stock of beluga is sufficiently recovering from unsustainable harvest during the early 1990s, and regulatory mechanisms are providing effective protection to assure conservation of the species. In the 2000 determination, the Service evaluated potential threats to beluga whales and determined that a listing was unwarranted. Based on our review of current information, nothing has changed to cause those threats to result in any different finding. The state urges a comprehensive conservation plan be coordinated with the state, finalized, and implemented, consistent with the Service's commitment in its 2000 determination.

Based on this information, the state urges the Service to find an ESA listing of the Cook Inlet stock of beluga whales is unwarranted at this time.

Sincerely,

Larry Hartig
Commissioner, Alaska Department of
Environmental Conservation

Tom Irwin

Development

Enclosures

OVERVIEW

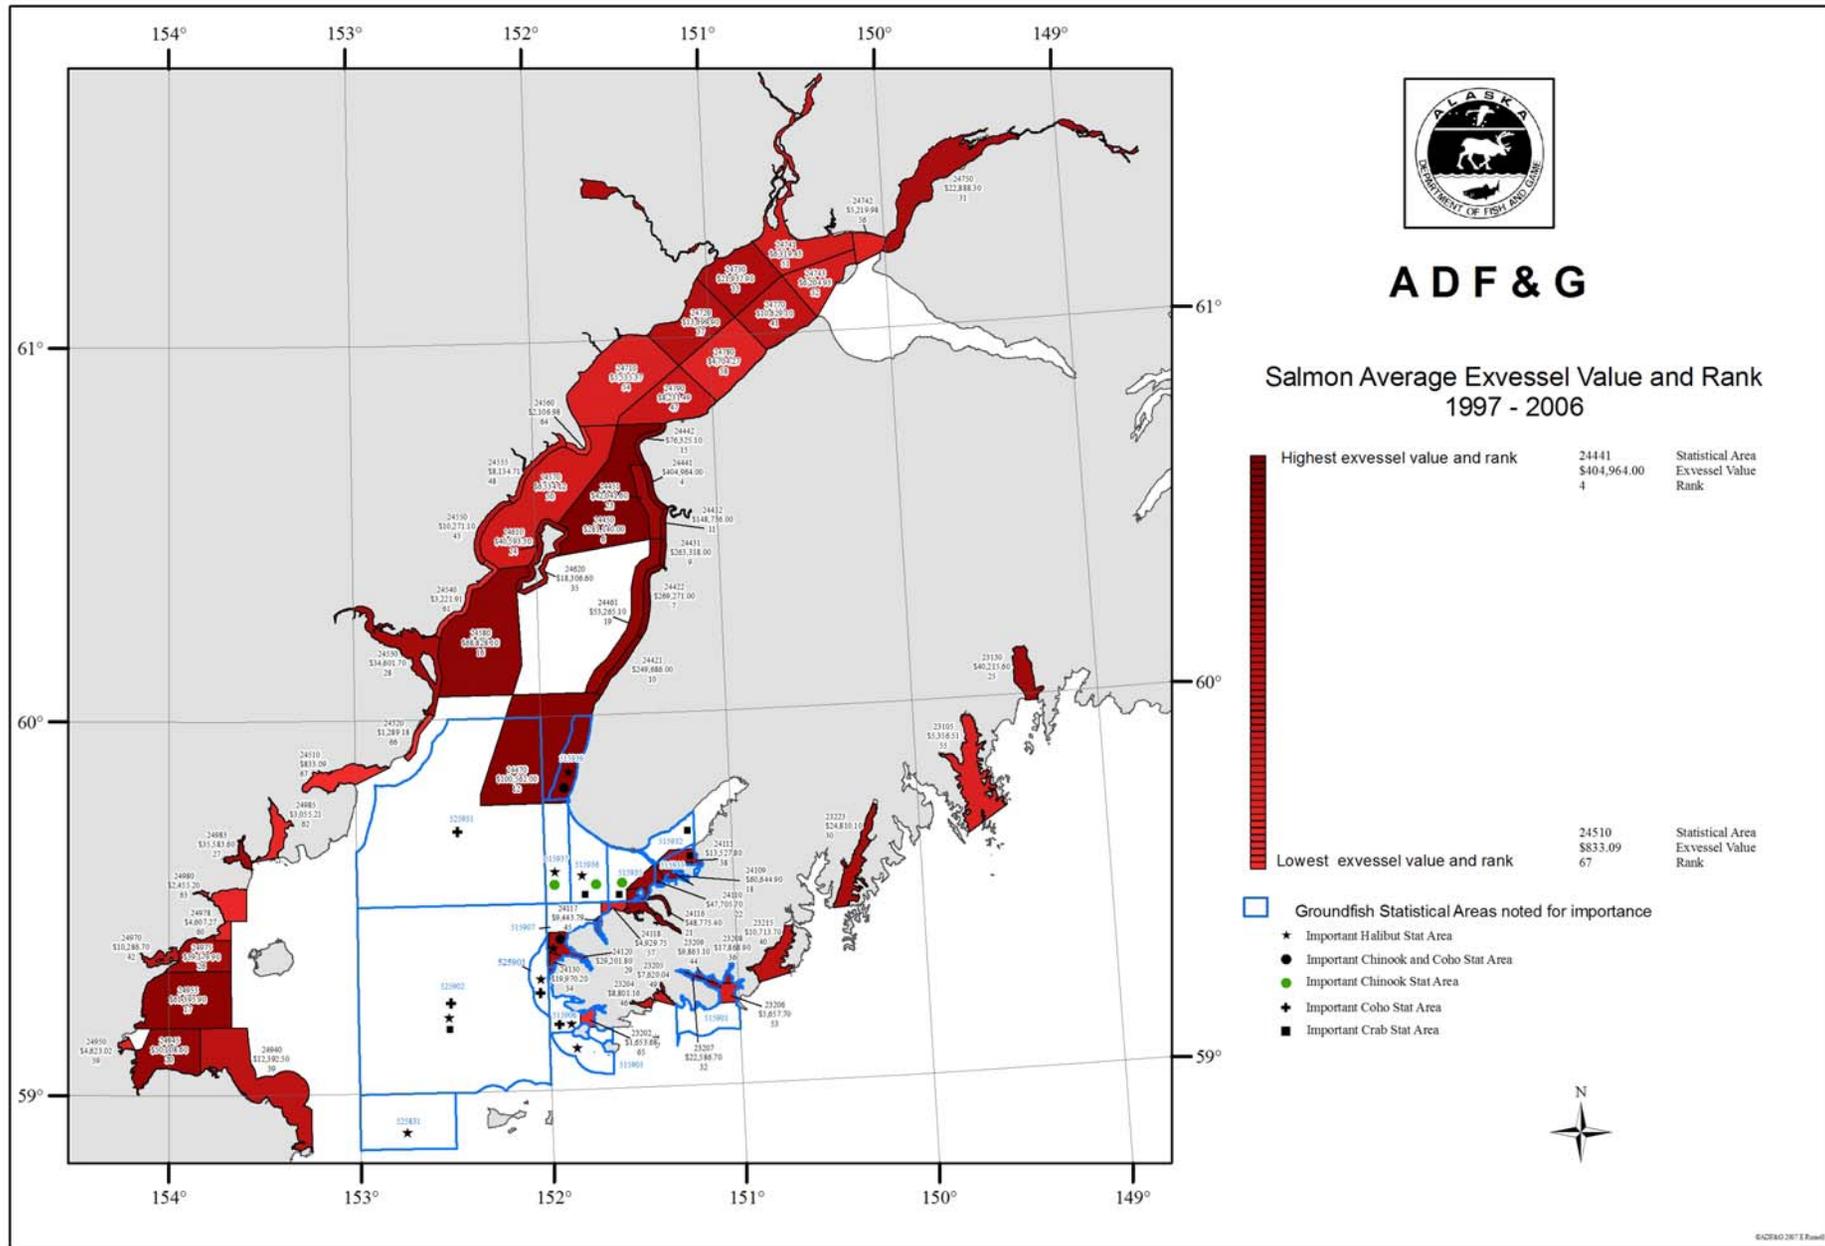

The National Marine Fisheries Service (Service) based its conclusion that “*the Cook Inlet beluga whale constitutes a distinct population segment (DPS) that is in danger of extinction throughout its range*” on the November 2006 “*status review and consideration of the factors affecting this species.*” The State of Alaska (State) comments provide information and analyses that were not considered by the Service in reaching this conclusion and demonstrate that the Service could and should have reached the significantly different conclusion that a listing as endangered under the Endangered Species Act (ESA) is unwarranted at this time. The State’s detailed comments on the proposal to list the Cook Inlet stock of beluga whales under ESA are enclosed and grouped in chapters according to the factors listed in the 2007 proposed rule (19854):

- Chapter 1: Current Population Status of the Cook Inlet Stock of Beluga Whale
- Chapter 2: Biological or Other Information Regarding Threats to the Species
- Chapter 3: Effectiveness of Ongoing and Planned Conservation Efforts by States or Local Entities
- Chapter 4: Identification of Critical Habitat or Essential Physical and Biological Features for this Species
- Chapter 5: Examples of Economic or Other Relevant Impacts of Designation of Critical Habitat.

These chapters also provide information and analyses to correct the November 2006 Status Review, which served as the basis for the Service’s proposed conclusion to list under ESA. Analysis of these factors and supporting information in the enclosed chapters results in the following conclusions:

- Both the Service’s determination in 2000 and the 2007 proposed rule refer to abundance estimates and calculations of decline and reproductive rates that were based on incorrect assumptions. Growth within the population could not reasonably be expected until the breeding age component of the population stabilized. This stabilization should not have been expected for at least 5 to 7 years after unsustainable hunting ended in 1999. Therefore, the abundance estimates and regression analysis inappropriately demonstrate a decline of 4.1 percent because the calculation starts in 1999, 5 to 7 years before reproductively mature whales make up a more normal portion of the population.
- We concur with Litzky (2001), cited in the Status Review, that a consistent recovery in the proportion of mature belugas might first be observed by 2004 and that the cumulative probability of observing recovery increases to >80 percent by 2007-2009. This prediction is reflected in the increasing counts of beluga whales in 2006 and 2007.
- The estimated risk of extinction for the most plausible models used in the Status Review was zero (0) at 50 years. The proposed rule concludes that Cook Inlet beluga whales are in danger of extinction based upon the continuing decline of the population and some statistical probability that the population is too small to be sustainable. The best available scientific and commercial data do not support this claim.

- Based on the recent Ninth Circuit Court of Appeals decision regarding Washington gray squirrel and the March 16, 2007, Department of the Interior Solicitor guidance regarding “significant portion of its range,” two separate standards must be met for a population to be considered a Distinct Population Segment. We find that the Cook Inlet stock of beluga whales does not meet these current standards and request reevaluation of the Service’s prior determination that the Cook Inlet stock of beluga whales constitutes a distinct population segment.
- The Service’s 2007 proposed rule concludes there have been no impacts to the Cook Inlet stock of beluga whales since the 2000 decision that a listing was not warranted. However, the proposed rule fails to also acknowledge the important and comprehensive regulatory measures that the state and federal agencies provide for the ongoing and future developments and activities in Cook Inlet. Instead, the rule is based on unsubstantiated speculation that developments and cumulative effects on habitat will increase beluga mortality. There are no scientific or commercial data or any other rational basis for concluding that present or future habitat conditions are slowing recovery of beluga whales or that they will result in cumulative impacts that affect its continued existence. To the contrary, today’s habitat protection standards are no less effective than past standards, and in some cases are superior, resulting in restoration of Cook Inlet habitat.
- The State requests the Service to coordinate with the State and others to finalize and cooperatively implement a conservation plan for the Cook Inlet stock of beluga whales. The Service committed in the 2000 rule to pursue such action with the State, other agencies, non-government organizations, and the public. The lack of progress during the intervening seven years needs to be immediately corrected in cooperation with the State and coordinated with other organizations to increase funding and implement important cooperative measures toward research and management of the beluga whales and their habitat. The adoption of a cooperative conservation plan would provide greater benefit for the Cook Inlet stock of beluga whales than is possible through an unwarranted listing and subsequent recovery plan.
- Extreme economic impact would occur to the residents, communities, and entire State of Alaska if Cook Inlet were determined to be critical habitat. This impact is discussed in Chapter 5. Attached is a map illustrating an example of the zones of economic importance of recreational and subsistence fisheries which are requested to be excluded from designation in the event that a determination to list is made.
- Over 15 million acres of protected land in and around Cook Inlet helps to protect whale habitat. The habitat in Cook Inlet supports healthy populations of fish on which beluga whales prey. These healthy populations of fish are evidenced by salmon returns to the river systems draining into Cook Inlet that continue to annually produce record numbers. These protected lands are comprised of State game refuges and critical habitats, special legislated management areas of the Upper Kenai and Recreational Rivers (Susitna), Chugach National Forest, Chugach State Park, and Katmai National Park and Preserve, among others. (See attached map).

State of Alaska Comments on ESA Beluga Listing
August 3, 2007, Enclosure
Overview, Page 4

Chapter 1

Current Population Status of the Cook Inlet Stock of Beluga Whale

The Status Review and 2007 proposed rule accurately summarize some of the available scientific information for the Cook Inlet stock of beluga whale. Relative to some marine mammal species in the Gulf of Alaska and Bering Sea region, the amount of information on the biology and ecology available for this stock of beluga whales is more limited. For the purpose of making a decision on whether the Cook Inlet stock of beluga whales should be listed as endangered with extinction, the pertinent available information acquired by the National Marine Fisheries Service (Service) on the population and its various parameters was accurately summarized. However, numerous calculations and conclusions need reconsideration based on additional information, inconsistency with established policy and rules, and the fact that the Service's conclusions are not consistent with information presented in the Status Review, proposed rule, and other available information.

Background

On July 13, 2000, the Alaska Department of Fish and Game (Department) denied an October 18, 1999, petition to list the Cook Inlet beluga as endangered under the State of Alaska (State) endangered species statutes. The Department's denial was upheld by the Alaska Supreme Court. In the 2000 denial of the petition, the Department laid out the following important historical information concerning the management and status of the Cook Inlet stock of beluga whales.

In the 1970s and 1980s beluga whales were seen during summer over a wide area in the upper and middle inlet, while in the 1990s they were seen in a smaller part of the upper inlet. The Department considered such a reduction of their range to be consistent with the reduced population size in the 1990s. Based on general biological characteristics of beluga populations, the Department determined the sustainable harvest level is likely 2 percent per year, or 7 animals from a population of 350, but the Department's estimate of population abundance indicated the population had declined over the previous 6-year period by 45 percent (approximately 7.5 percent per year) and the Service had estimated the average kill during 1995-1997 at 87 per year. (These estimates vary from one federal register publication and Status Review to another between 2000 and 2007, but are within a relatively constant range.)

At the time of the 1999 petition under State law, the Department was actively involved in monitoring the Cook Inlet stock of beluga whales because State laws require that all populations be managed on a sustained yield basis. However, the State's ability to manage the harvest of the population had been preempted by federal law, the Marine Mammal Protection Act (MMPA). Had the Service not agreed in 2000 with the State's petition to list the stock as depleted under the MMPA and adopt regulations to restrict subsistence harvest, the State was prepared to pursue actions to protect the Cook Inlet stock. Recognizing that the Service had taken action, the State concluded that the population was not threatened with extinction. The Service concluded that the 1999 population estimate, following the hunting moratorium in 1998, gave a preliminary indication that the population was in recovery (65 FR 38788-790 (2000)). The Department's view was more conservative than the Service's, but it agreed that efforts to limit harvest would

eventually result in population recovery since no other factors were individually or collectively affecting the health of the population. The Department concluded that the population would be likely to recover slowly, hunting would have to be limited for a long time, and the population managed conservatively.

The State had previously acted to place much of the important beluga habitat within Cook Inlet in protected status, including several state game refuges and critical habitat areas. (See Chapter 3) Recent actions by the Alaska Department of Natural Resources had maintained protection of important habitat by removing it from lease and sale offerings, even though there was no evidence of any habitat decline or habitat-related cause for the population decline. Among other purposes, the habitat protection measures were anticipated to aid in beluga population recovery once the unsustainable harvest was stopped. Those habitat protection measures remain in effect today along with additional regulatory measures subsequently adopted.

2007 Proposal Contradicts 2000 Finding that a Listing is Unwarranted

The 2007 proposed rule (19855) to reverse the 2000 determination, that an Endangered Species Act (ESA) listing was not warranted, is based in part on the following (quoted):

The 2000 determination that ESA listing was not warranted was premised on at least two findings that justify further review. First, the only factor then known to be responsible for the decline in beluga abundance was subsistence harvest. Second, the 2000 Status Review used simulation modeling efforts that demonstrated this DPS is not likely to decline further if the harvest was reduced and an annual increase of 2 to 6 percent were assumed. Abundance estimates since harvest management began in 1999 have declined at an average rate of 4.1 percent per year, challenging the original findings.

In addition, the International Union for the Conservation of Nature and Natural Resources (IUCN) assessed the status of the Cook Inlet beluga whale in 2005 (Lowry et al, 2006). The IUCN determined that this population had a 71 percent probability of having a negative growth rate (in 2005) and met its criteria for critically endangered status.

We offer the following regarding these considerations.

First, nothing in the biological or physical environment has changed since 2000 regarding the five factors or “threats” under ESA that would justify a change to the previous conclusion that unsustainable harvest was the only factor responsible for the decline in beluga abundance. The status of these five factors is discussed in Chapter 2, and our review concludes that an ESA listing is still unwarranted based on those factors individually and cumulatively.

Second, both the 2000 and current abundance estimates and calculations of decline and reproductive rates contain a number of assumptions that need correction, which we discuss below. The impacts of the significantly disproportionate harvest of reproductive adults prior to 1999 were not previously recognized. As a result, the original assumption that an increase would be evident in increased abundance estimates within a year of restricting harvest was flawed.

Growth within the population could not reasonably be expected until the breeding age component of the population stabilized, and this stabilization could not be expected for 5 to 7 years after unsustainable hunting ended. These issues are further discussed later in this chapter.

Third, the IUCN is a United Nations established organization to evaluate worldwide populations and is composed of selected scientists who generate assessments using criteria for certain status rankings that are not comparable to the ESA determinations. Because the IUCN calculations are based on different factors and are not subject to the agency scientific criteria for decisions required to be used in ESA, the IUCN assessment is a concern but has no bearing on an ESA listing decision. The June 22, 2000, determination clearly recognized the inappropriateness of using the IUCN assessment (38779): “

Although the IUCN criteria are appropriate to identify species that may need conservation measures, they do not include the full range of factors that are included in the ESA; therefore, they are not appropriate for a determination of the status of a stock under the ESA.

In preparing this 2007 proposed rule, the Service considered its update of the earlier Status Review and the 2006 petition to list under ESA. The “Summary” in the proposed rule (19854) concluded “*the Cook Inlet beluga whale constitutes a distinct population segment (DPS) that is in danger of extinction throughout its range*” based on the findings from the November 2006 Status Review and consideration of the ESA factors affecting this species. The State provides information and analyses that were not considered by the Service in reaching this conclusion. Although the November 2006 Status Review overall provides a fairly comprehensive review of information on the Cook Inlet stock of beluga whales, the 2007 proposed rule reflects omissions, errors, and unsubstantiated interpretations. We note that some include incorrect facts or unresolved comments that were provided by the State and public on the earlier draft Status Review and draft conservation plan.

The State concludes that, upon review of these comments, the Service must determine that no information on the population status has been acquired subsequent to the June 22, 2000, determination to justify a change in the Service’s previous decision that an ESA listing is not warranted at this time. The 2000 assumptions for predicting a recovery were too optimistic (discussed below), but the conclusion of the 2000 rule was sound.

The 2007 proposed rule and its underlying Status Review discuss and request comments on the following topics:

1. Scientific and Commercial Information Regarding Population Abundance and Trends
2. Population Modeling
3. “Species” Identification under ESA as a Distinct Population Segment
4. Geographic Range of the Species
5. Extinction Risk Analysis

In the remainder of this chapter, the State provides additional information and analyses regarding the above topics:

1. Scientific and Commercial Information Regarding Population Abundance and Trends

According to the 2007 proposed rule (19855), “*comprehensive, systematic aerial surveys on beluga whales in Cook Inlet began in 1993.*” Also, according to the proposed rule (19856) the population estimates prior to 1994 (i.e., 1979 and 1993) are unreliable because of “*differences in survey methods and analytical techniques prior to the 1994 survey.*” Based on the 1994-1998 surveys, the 2007 rule (19855) concludes: “*These surveys documented a decline in abundance of nearly 50 percent between 1994 and 1998, from an estimate of 652 whales to 347 whales (Hobbs et al., 2000).*” The latter estimated decline in abundance is the “*best available scientific and commercial information*” for that period of time. However, the 2007 proposed rule and the 2006 Status Review use three calculations in the analyses of Cook Inlet stock of beluga whales that need adjustments prior to being relied upon for the 2007 decision concerning the Cook Inlet beluga whale population status.

- A. One of the calculations that needs correction involves inappropriate use of the 1979 estimate to establish carrying capacity, which used in the proposed rule (19856): “*indicates a 77 percent decline in 27 years, but with unspecified confidence.*”

While we appreciate the qualification that the estimate has “unspecified confidence,” we suggest the use of the 1979 figure should not be relied upon and is misleading in depicting trends. Elsewhere the 2007 proposed rule (19855) confirms that there was no reliable abundance survey conducted prior to 1994.

One estimate of historical abundance is based on: “*Portions of Cook Inlet surveyed during 1979 resulted in an abundance estimate of 1,293 beluga whales (Calkins, 1989).*” The 1979 beluga estimate (often rounded to 1300) should not be used for purposes of establishing either Cook Inlet carrying capacity or an assessment of trends of the Cook Inlet stock of beluga whales. The May 31, 2000, final rule (34596-34597), which determined the stock is depleted under MMPA, provided extensive discussion on a proposed range of figures (653-1300) that could all be deemed at that time to be the best available scientific information upon which to establish the historic abundance and carrying capacity, depending upon correction factors. For example, Calkins (1984) proposed using a correction factor of 2.7 for the 1979 count, which was the correction factor developed for beluga surveys in Bristol Bay where water, weather, and physical features differ from that in Cook Inlet.

While all of the figures and information from long-time residents and State surveys used to project historical abundance do provide valuable snippets of information, none are reliable estimates of carrying capacity because other factors, e.g., habitat, prey abundance, and predation, are not similarly analyzed for reliable historic information. Depending upon one’s assumptions, carrying capacity was probably under 1000 for most years, but it could have just as easily been well over 1300 in other years. Even if the Cook Inlet population was 1300 in the late 1970s, that number may greatly exceed today’s carrying capacity. Information available through NOAA involvement in assessing other populations throughout the south central and western coast of

Alaska indicate significant changes in water temperature, marine mammals, and prey populations occurred during this same period in the late 1970s. Likewise, fisheries management by the State beginning in the 1960s stabilized fish returns so there were less cyclic highs and lows which may be related to historical accounts of beluga population oscillations.

Population modeling that uses the 1979 estimate to establish historic abundance and set a carrying capacity (“K”) for Cook Inlet should not be viewed as the “*best available scientific and commercial information.*” The underlying counts of 200-500 beluga whales conducted by the Department can be cautiously compared to others from the 1960s through the early 1980s (May 31, 2000 rule, p. 34596) in order to evaluate trends. The Department estimated the carrying capacity to be less than 1,000 during that time period. Better estimates of carrying capacity need to be calculated based on an ever-growing set of available data for the Cook Inlet area. This includes recognition that the carrying capacity of Cook Inlet may vary seasonally and may include areas outside of Cook Inlet as the population increases.

The uncertainty of the single data point from 1979 and other back-calculated estimates is reflected in the April 6, 2004, final rule (17978) decision by the Administrative Law Judge, derived during considerations by the Assistant Administrator in hearings on Alaska Native take that established the carrying capacity as follows:

(2) Carrying Capacity. Based on the evidence adduced at the hearing, NMFS would need a number of years of annual abundance estimates to accurately determine the carrying capacity of CI beluga whales with any reliable degree of certainty. However, NMFS believes the estimate of carrying capacity presented in the EIS is reasonable for interim management purposes.

Those management purposes after the moratorium and depleted listing under MMPA were to regulate subsistence harvests that slowed, but did not preclude, recovery of the population to reach a desired population level. **The carrying capacity calculation served that purpose but is a misleading data point for demonstrating statistical trends, such as the “77 percent decline” stated in the proposed rule.**

- B. Another calculation that needs reconsideration involves the assumption that the surveys in 1994-1998 can be treated equally in making population estimates as the surveys conducted after the moratorium on hunting.

Although the 1994-1998 estimates of abundance were sufficient to demonstrate a significant decline, the subsequent estimates would not be expected to reveal a rebound during the first generation after the moratorium. The increase in hunting in the early 1990s primarily targeted large (older) white (reproductively mature) adults that are easy to see from shore and boats. The surveys conducted in the first years after the moratorium, which also primarily count white, reproductively mature whales, count a disproportionately smaller part of the population because of the difficulty seeing the younger whales that also have higher mortality. After the moratorium, the harder to see dark or grey immature whales made up a greater portion of the significantly reduced population for several years. **Some adjustments may have been made to calculations of count estimates and several runs of the models attempted to speculate what**

this proportion of immature whales might be, but these adjustments are based on varying assumptions with no means to verify the resulting estimates.

- C. Another calculation that needs correction involves the reliance on the 2000 Status Review's expected growth rate increase of 2 to 6 percent beginning in 1999.

A determination of which year's population estimates will be used as a starting point to calculate trends of the population after the legislated hunting moratorium on May 21, 1999, is a particularly important and largely overlooked consideration. According to the final May 2000 rule issuing the depleted finding (34592), the Status Review "*clearly shows that the harvest from 1994 through 1998, the period when reliable abundance estimates were available, was sufficient to account for the decline.*" The State concurred with this conclusion reached through cooperative assessments begun in 1998. In fact, based on these cooperative assessments, the State petitioned the Service on January 21, 1999, to designate this stock as depleted under the Marine Mammal Protection Act.

As described in "B" above, the surveys conducted in the first years after the moratorium counted a disproportionately smaller part of the population because of the difficulty seeing the younger whales and their lower survival. After approximately 50 percent of the estimated population was killed in 4 years and the majority of those were reproductive adults, the younger generation should not have been expected to be reflected in count estimates in the first few years after the moratorium. Although the proposed rule (19855) explains a number of factors that were considered and modeled in the 2006 Status Review, it was too optimistic to calculate the recovery would have been expected as early as 1999. **In fact, given that the moratorium took effect in 1999 and the previous four years' calves likely had a low survival rate, an expected growth rate increase might not even be expected for one full generation. This is consistent with the result of Litzky (2001) indicating that it would take 5 to 7 years to begin recovery.**

Based on the calculation problems discussed in "B" and "C" above and the lower survival of young whales considered in the various modeling exercises, we should not have expected to see a recovery reflected in increased counts until approximately 2005 (6th year after the moratorium). The anticipated recovery will be evident if continued increases in the count estimates occur in successive years beginning in 2005, not beginning in 1999. Therefore, the abundance estimates and regression analysis used in the Status Review and public presentations during the comment period inappropriately demonstrate a decline (4.1%) because the calculation starts with 1999 and does not account for the high likelihood of undercounting immature and hard to count whales, which experience lower survival rates than adults, for a generation before reproductively mature whales begin to make up an increasing portion of the population.

Additional Rate of Growth Consideration

The April 6, 2004, final rule (17978), which adopted the recommendations of the Administrative Law Judge regarding establishing harvest quotas for Native Alaskans, provided specific guidance to the Service in evaluating the rate of growth of the population, as follows:

(3) Intrinsic Rate of Growth (R_{max}). R_{max} is the maximum net productivity rate of CI beluga whales on an annual basis. R_{max} is derived by subtracting natural mortality from the gross annual reproduction rate. NMFS determined that 4 percent, amounting to 10 to 12 marine mammals added to the population on an annual basis, is reasonable for cetacean populations similar in size to the CI beluga whales. However, R_{max} for CI beluga whales will be reassessed as new data become available.

The Service's calculation of a 4 percent rate of growth exceeds the Department's conservative estimate of 2 percent rate of growth. However, the Service negotiated a harvest that more closely approximates 1/2 percent per year. If one to two beluga whales were harvested by Native Alaskans annually (5 were harvested over the past 8 years) and predation totaled the predicted one beluga per year (projected in the 2007 proposed rule), the population would slowly recover as predicted by the Department. But this recovery for the first generation after the moratorium would not be at the 2 to 6 percent predicted by the 2000 Status Review, reflected in the 2000 rule, and assumed for the modeling.

2. Population Modeling

The methodology used to estimate abundance and trend in the Status Review is well-thought out and rigorous, but a number of adjustments are needed in the assumptions for the models. The population viability analysis (PVA) approach used by Hobbs et al. is sophisticated, but highly parameterized. As such, the authors were forced to borrow several data inputs from adjacent beluga populations, which is a common modeling practice but is not Cook Inlet data. The models assumed the harvest was targeted at adults only and they accounted for lags in maturation time by using an age-structured model. The authors reference Litzky (2001), whose results indicate that the adult to juvenile ratio takes 5-7 years to recover.

The bottom line is that the structure and incorporation of uncertainty of modeling was adequate, but the assumptions used and interpretations made relative to the timing of recovery are not, for the following reasons:

- Used insufficient time during the recovery period (1999+) to assess the true trajectory of the population
- Risk of extinction in the near term (50 years) for all reasonable models was zero, indicating high uncertainty in the trajectory of the population
- Listing decision is missing an assessment of the risk of making a determination that listing is not warranted at this time; a new petition could be filed or the Service could initiate its own review in a few years when more reliable information about the recovery trajectory, based on current survey techniques, is available

The model incorporates a time lag between the reduction in mature animals in the population during the period of high harvest (1994-1998) and the potential recovery of the population from these removals. However, the assessment of extinction risk does not take into account the possibility that the time period after harvest was virtually eliminated (1999-2006) was insufficient to detect the end of the lag period (or conversely the beginning of the recovery

period). Specifically, the Status Review indicates that a recovery of 2% to 6% per year was anticipated during 1999-2005 as a result of curtailed hunting. Given the population dynamics of belugas and the modeling work done in the Status Review, we disagree that an increase in abundance of 2% to 6% during 1999-2005 would be anticipated even if the population was recovering from the harvests of 1994-1998.

The period of hunting removed a significant number of mature animals from the population that likely limited recruitment in succeeding years. It also may have resulted in loss of calves up to 14 months of age whose mothers were killed. **It is more likely and is demonstrated in one of the papers cited in the Status Review (Litzky, 2001) that we might first observe a consistent recovery in the proportion of mature belugas by 2004 (Fig 2.8 of Litzky 2001) and that the cumulative probability of observing recovery increases to >80% by 2007-2009 (Fig 2.9 of Litzky 2001).** A recovery in the proportion of mature belugas would be a portent of recovery, with recovery of abundance coming later as recruitment increases.

The aforementioned observations combined with the outcomes of models of extinction risk in the Status Review indicate that a determination is premature. We suggest that a sensitivity analysis and risk assessment be made that weighs acting on listing now against the additional risk to the population by waiting for maturity and abundance data in the next 2-3 years that could significantly change the outcome of the risk of extinction analysis. **There is some indication from the Status Review that waiting a few years for these additional data will not increase risk of extinction because the estimated risk for the most plausible models was zero (0) at 50 years** (Table 6 of the Status Review).

3. “Species” Identification under ESA as a Distinct Population Segment within All or a Significant Portion of its Range

Approximately 100,000 beluga whales inhabit the waters off the Alaska coast. They are separated into five mostly distinct populations or stocks based on summering areas. All of these populations are classified as *Delphinapterus leucas*. No subspecies designations have ever been published.

Molecular genetics studies have shown Cook Inlet stock of beluga whales have different mitochondrial DNA (mtDNA) haplotype frequencies than the other four beluga stocks identified in Alaska. However, mtDNA haplotype frequency differences indicate limited gene flow for females only. Even though the Cook Inlet stock of beluga whales appears to be spatially isolated from other stocks, this is not really known because tagging studies are very limited and seasonal ranges and movements are not well characterized.

Male mediated gene flow in beluga whales demonstrates substantial exchange among stocks once thought to be discrete based solely upon mtDNA data (Brown Gladden et al. 1999).

2000 rule: DPS justification

Under the federal Endangered Species Act of 1973, “species” was originally defined to include “any subspecies of fish or wildlife or plants and any other group of fish or wildlife of the same

species or smaller taxa in common spatial arrangement that interbreed when mature.” Amendments in 1978 resulted in the language in which a “species” was defined to include “*any subspecies of fish or wildlife or plants, and any distinct population segment of any species of vertebrate fish or wildlife which interbreeds when mature*” (emphasis added). Based on the 1978 amendment, the Service and the Fish and Wildlife Service developed a policy regarding the recognition of a distinct population segment under the federal ESA. The Cook Inlet stock of beluga whale was designated a Distinct Population Segment (DPS) by the Service in 2000, based on the joint Service and Fish and Wildlife Service policy that was in effect at that time, which considered three elements: (1) population discreteness, (2) population significance, and (3) conservation status of the population. Subsequent to 2000, the criteria for federal designation of a DPS have evolved due to court decisions, several solicitor interpretations and policy revisions, largely resulting from guidance in recent court decisions.

The Service’s determination that an ESA listing was unwarranted in 2000 included a justification for their opinion that the Cook Inlet stock of beluga whales should be considered a DPS, citing O’Corry-Crowe at al. (1997). This position is echoed in the 2006 Status Review and other publications without further analysis or applying current standards and policies.

Scientific problems with the 2000 DPS finding

Because mtDNA only reflects female ancestry and gene flow, it is not the best marker to quantify gene flow and exchange of individuals among populations over time. Nuclear markers (e.g., allozymes, microsatellites, minisatellites, SNPs, etc.) are bi-parentally inherited and offer a more complete picture of gene flow among populations over generational time scales. Numerous publications document that matriarchal lineages identified with mtDNA mask population connectivity (male gene flow). In species that exhibit strong female philopatry, male-mediated gene flow is arguably the most important factor in maintaining genetic continuity among populations.

The Service has conducted numerous status reviews of other candidate species that incorporated evidence from nuclear DNA studies; absence of nuclear DNA data is a fatal flaw in the status review of beluga whales. However, even if further analysis of nuclear DNA data show allele frequency differences, this would not necessarily mean the Cook Inlet stock is a DPS because criteria to designate DPS are subjective.

The State shares trust responsibility with the Service for the sustainability of beluga whales in Alaska. During the public comment period, the Department requested the original genetic data used for the various genetic interpretations contained in the 2006 Status Review upon which the 2007 proposed rule is based. To date, that information has not been provided. Additional comment will be provided based on any additional analyses derived once those data are provided by the Service. We also understand that the Service has acquired additional information from nuclear DNA studies that was not discussed in the Status Review or proposed rule, which we will also address when the data are available.

Current DPS standards

Based on the recent Court of Appeals decision regarding application of the joint Service and Fish and Wildlife Service DPS policy to the Washington gray squirrel, Northwest Ecosystem Alliance

v. U.S., 475 F.3d 1136 (9th Cir. 2007) and the March 16, 2007, Interior Solicitor guidance on the meaning of “*In danger of extinction throughout all or a significant portion of its range*” (although not the same agency, federal interpretation of the same law should be consistent), two separate standards must be met to be considered a DPS: 1) discreteness, and 2) significance. Geographic isolation can, by itself, satisfy the discreteness factor, but it does not resolve the significance factor.

Significance of the population segment to the species to which it belongs offers considerable room for debate and involves a number of non-exclusive factors. Loss of a geographically isolated peripheral population of a species, “*even where it would result in a serious reduction in the range of the species,*” may not be “*of biological and ecological significance to the taxon as a whole.*” 475 F.3d at 1146-49. Similarly, even clear genetic differences between populations may not be significant where genetic makeup does not differ “*markedly*” from that in other populations. 475 F.3d at 1149-50. Congress directed (SR 151, 96th Congress, 1st session) that the authority to list DPS is to be used “*sparingly*” while encouraging the conservation of genetic diversity.

The National Marine Fisheries Service and U.S. Fish and Wildlife Service will consider available scientific evidence of the discrete population segment’s importance to the taxon to which it belongs. This consideration may include, but is not limited to, the following:

- A. Persistence of the discrete population segment in an ecological setting unusual or unique for the taxon,
- B. Evidence that loss of the discrete population segment would result in a significant gap in the range of a taxon,
- C. Evidence that the discrete population segment represents the only surviving natural occurrence of a taxon that may be more abundant elsewhere as an introduced population outside its historic range, or
- D. Evidence that the discrete population segment differs markedly from other populations of the species in its genetic characteristics.

Both agencies also argue that, because precise circumstances are likely to vary considerably from case to case, it is not possible to describe prospectively all the classes of information that might bear on the biological and ecological importance of a discrete population segment.

The Cook Inlet stock of beluga whales is relatively isolated, does not markedly differ from other belugas more abundant elsewhere, and is likely a remnant stock on the southern edge of its range. As such, the stock is not critical to the survival of the species and, contrary to opinions expressed in Service documents, does not occur in an ecologically unusual or unique setting compared to the other estuarine and bay habitat occupied by the other stocks along the Alaskan coast during summer. Consequently, we conclude that the loss of the population would not result in a “significant gap” in the range of the taxon. Clearly, Cook Inlet is not a “significant portion of the range” for the beluga whale, based on the March 16, 2007, Solicitor guidance.

We detect a disturbing trend of preferential designation of DPS for ESA listings in Alaska. The eastern and western Alaska stocks of Steller sea lion, the western Alaska stock of sea otter, and

now the Cook Inlet stock of beluga whale have all had DPS designated and are either listed or proposed for listing under ESA. In each case, genetic distinctness is claimed in the proposed rules without acknowledgement that this is subjective. Because geographic separation (without genetic differentiation) may be sufficient to designate DPS, this may seem like an academic argument, but it is not. The subjective declaration of genetic distinctness should be openly acknowledged to meet the standard of presentation of the best science in ESA considerations.

4. Geographic Range of the Species

The May 31, 2000, rule (34597) identified the range of this stock, as follows:

§216.15 Depleted Species

(g) Cook Inlet, Alaska, stock of beluga whales (Delphinapterus leucas). The stock includes all beluga whales occurring in waters of the Gulf of Alaska north of 58° North latitude including, but not limited to, Cook Inlet, Kamishak Bay, Chinitna Bay, Tuxedni Bay, Prince William Sound, Yakutat Bay, Shelikof Strait, and off Kodiak Island and freshwater tributaries to these waters.

We understand that the Service may change this definition in the final rule. The sources cited in this proposed rule reference numerous mixed claims of geographic range of this stock. The 2007 proposed rule states (19856) the Service intends to exclude the Yakutat pod even though it is related to the Cook Inlet stock. While we believe that these belugas have the potential to contribute to the Cook Inlet stock, we agree that, if a decision to list is made at this time, based on available information it would be inappropriate to include this widely dispersed pod or any others that periodically are observed outside of Cook Inlet in the listing. One viewpoint is that the Cook Inlet population is a remnant or widely-dispersed population separated from the other Alaska stocks as the ice retreated. Others theorize that the Alaska beluga stocks winter together, and the Cook Inlet beluga whales could travel that far because publications indicate beluga travel many hundreds of miles. The current lack of observation in lower Cook Inlet may be a factor of less traffic in winter compared to summer. These questions need to be addressed through further research and monitoring. The 2007 proposed rule (19857) concludes that the proposed ESA listing only applies to beluga whales found in Cook Inlet and not those found outside of the Inlet in the Gulf of Alaska. There is no discussion of how a listing will affect Section 7 consultation requirements when the population expands and theoretically increases dispersals and movements throughout the Gulf coastline.

5. Extinction Risk Analysis

A Population Viability Analysis (PVA) conducted by the Service indicates a “high probability” (26%) of extinction in 100 years, based on ‘behavior’ of a population of less than 500 whales. A separate analysis by Dan Goodman for the Marine Mammal Commission indicates that for 1999-2005, the probability that the population is declining is 71.2% and the estimated rate of decline is 3.74%. We suggest that both of these analyses of probability are based on assumptions that need

revision to reflect 2007 data and to eliminate the 1999 and 2000 data, when the population was declining directly due to the overharvest effects on calf survival.

We have a number of general comments regarding the modeling aspects of the PVA and the related information in the Status Review.

- A detailed discussion of the assumptions used in developing and conducting the modeling, including justification of the assumptions, the ramifications of the assumptions with respect to the results, and the consequences of violating the assumptions is needed, including a sensitivity analysis. In particular, the catastrophic loss assumption is excessively high, with no basis in historical evidence, and that estimate alone significantly influences the extinction risk analysis. The modeling includes uncertainty in the inputs, which provides the numerous population trajectories. If the uncertainty around each input was modeled correctly, then a sensitivity analysis is superfluous. A list of inputs and their respective modeled distributions are needed in order to assess this need.
- The analyses provide good documentation of the behavior of the models, but how well these results imitate the dynamics of the Cook Inlet stock of beluga whales, especially in the distant future, might be a function of the assumptions associated with the models.
- A very clear discussion of these assumptions would be invaluable in assessing how reasonably the simulations approximate reality.
- The Status Review does not adequately address the potential impact of an age distribution skewed toward juveniles as a result of the high mortality of adults from the 1994-1998 subsistence harvest. The modeling work addresses this issue in part, but the proposed rule does not explain it. The population assessment's attempt to estimate age distribution from images obtained on the videos during surveys, in which young whales are hard to see.
- The risk analysis in the 2006 Status Review (and Goodman's review¹ of 1999-2005) is based on a population trajectory determined from the abundance data. However, the abundance data from 1999-2005 would be expected to indicate a negative population trajectory because the population would still be recovering from high harvests of mature animals during 1994-1998. Population modeling in the Status Review and a review of recovery timing by Litzky (2001) indicate that the beluga population would not show the first signs of recovery (i.e., an increase in the proportion of mature animals in the

¹ Dan Goodman submitted an updated review on July 27, 2007, which reiterates that the population is declining and adds that more years of data (2003-2006) have reduced the uncertainty about the decline. However, Goodman also attempts a simple count-based PVA on the adult data and deaths due to hunting without considering the age structure of the population and the lag between adulthood and subsequent recruitment. This is not a defensible analysis and is probably why the Service uses a more complex demographic model in the Status Review. Goodman's 2007 paper also has an error in the abundance table (Table A1. 1999 datum should be 367, not 967). The Goodman review also ignores the question of how much change in adult abundance in the near term (next 2-3 years) is necessary to change the outlook from a decline to an increase in the rate of change.

population) until at least 2004 and the probability of observing an increase in the proportion of mature animals would not exceed 80% until sometime between 2007 and 2009. A recovery in the proportion of mature belugas would be a portent of recovery, with increases in abundance coming later as recruitment increases.

We suggest that a sensitivity analysis and risk assessment be made that weighs the risk of making a determination that listing is not warranted at this time, recognizing that better data regarding population abundance and trajectory will be available within a few years and that a new petition for listing could be submitted, or the Service could reinstate review on its own initiative at that time. Maturity and abundance data that will be available in the next three to five years could significantly change the outcome of any risk of extinction analysis. There is some indication from the Status Review that waiting a few years for these additional data will not increase risk of extinction because the estimated risk for the most plausible models was zero (0) at 50 years (Table 6 of the Status Review).

Chapter 2 **Biological or Other Information Regarding Threats to the Species**

This chapter provides information and analyses to supplement or correct information considered by the National Marine Fisheries Service (Service) in the 2007 proposed rule and contained in the underlying November 2006 Status Review. Through the regulatory process, the Service is required to determine whether a species is likely to be in danger or threatened with extinction because of any one or a combination of the following factors (19857):

- (1) The present or threatened destruction, modification, or curtailment of its habitat or range;*
- (2) Overutilization for commercial, recreational, scientific, or educational purposes;*
- (3) Disease or predation;*
- (4) The inadequacy of existing regulatory mechanisms; or*
- (5) Other natural or manmade factors affecting its continued existence.*

The State of Alaska (State) agrees with the Service's conclusion in the proposed rule (19858) and in its supporting materials that factor "**(2) overutilization**" is not contributing to either the current status or potential endangered status of Cook Inlet beluga whales. Unregulated harvest contributed to the low population level in 1998. Indications are that the population has stabilized since harvest was regulated, and full recovery is expected (See Chapter 1).

The Service expresses concern that overutilization could occur if commercial and recreational whale watching increases in the future. This same concern was expressed in the 2000 final rule determining that the stock of whales is not endangered; however, no water-based whale watching occurred then or now in fresh or marine waters of upper Cook Inlet. Anyone conducting commercial day-use activities on State waters is required to register their activities. According to the Alaska Department of Natural Resources, no companies have registered commercial whale watching activities within State waters in upper Cook Inlet since the regulation became effective. According to the Alaska Department of Fish and Game, permits are also required for commercial activities within Special Designated Areas, and no permits for whale watching have been requested within State Refuges or State Critical Habitat Areas in upper Cook Inlet (See Chapter 3 for map and further discussion).

Regarding **the other four factors listed above**, the Service, after taking into account conservation efforts, concludes in the proposed rule (19860):

. . . that the Cook Inlet beluga whale is in danger of extinction throughout all of its range because of: present or threatened destruction, modification or curtailment of habitat or range; the inadequacy of existing regulatory mechanisms (largely the past absence of regulations on subsistence harvests); disease and/or predation (further predation by killer whales can be shown to have a significant impact on survival); and other natural and manmade factors affecting its continued existence (effects of past subsistence removals).

We disagree, as addressed for each of the remaining four factors below.

Factor “(1) *The present or threatened destruction, modification, or curtailment of its habitat or range*”

The Service’s conclusion in the proposed rule (19858) is correct that:

No information exists that beluga habitat has been modified or curtailed to an extent that it is likely to have caused the population declines observed within Cook Inlet.

Based on this conclusion and the supporting information, the Service should determine that listing the Cook Inlet stock of beluga whales as endangered is not warranted at this time.

As described in the Service’s proposed rule and Status Review, the current habitat conditions have been relatively constant since the large scale developments of the 1970s. Since the 1970s, the State and federal agencies implemented additional regulatory measures, including land use plans and implementing regulations, oil spill contingency plans, and restrictive permitting conditions for developments and for other public activities in order to increase protection of the marine and freshwater habitat. This land stewardship is codified, implemented, and enforced by a number of federal, state, and local agencies. These protective regulatory mechanisms are particularly evident in State permitting requirements designed to protect water quantity and quality that is fundamentally important to the habitat for healthy salmon populations, which in turn serve as primary prey for beluga whales. Although the proposed rule concludes there have been no impacts to the Cook Inlet habitat since the 2000 decision that a listing was not warranted, the proposed rule fails to acknowledge that these important and comprehensive regulatory measures will continue to provide environmental protection so that ongoing and future developments and activities do not affect beluga whale habitat.

As quoted above, the proposed rule recognizes growth and development which have occurred to date did not contribute to beluga whale population declines, but the Service speculates that (19858) “*concern is warranted for the continued development within and along upper Cook Inlet and the cumulative effects on important beluga habitat.*” Concern is always present, which is why we regulate the developments for both present and cumulative effects, but that does not provide sufficient basis for a prediction of endangerment so long as the comprehensive regulatory measures continue in effect.

The proposed rule (19858) describes four developments currently under consideration for construction in Upper Cook Inlet “*which may have adverse consequences*” and two “*ongoing activities that may impact this habitat*” (oil and gas activities and developments and industrial discharges or pollutant spills). The Service applies its extinction risk assessment (See State comments in Chapter 1) and, without evaluating improvements since 2000 leading to the existing regulatory mechanisms applicable to these developments and activities, concludes: “*Therefore, threatened destruction and modification of Cook Inlet beluga whale DPS habitat contributes to the proposed endangered status.*” No reasonable basis is provided to assume that these developments, either individually or cumulatively, will destroy or modify the habitat. This conclusion is an uncharacteristic deviation away from the factual assessment contained in the proposed rule, which recognizes past activities did not contribute to the beluga population

declines in the 1990s. This deviation toward an unsubstantiated projection that future and ongoing activities would contribute to increases in mortality despite continued habitat management measures is scientifically unfounded.

The State provides information in subsequent chapters on current beluga habitat and concludes there are no scientific data that indicate “present or threatened” impacts on essential features of beluga habitat will occur due to the two ongoing and four proposed developments described in the proposed rule. There are no scientific or commercial data or any other rational basis for concluding that present or future habitat conditions are slowing the recovery of beluga or will result in cumulative impacts that affect its continued existence. To the contrary, today’s habitat protection standards are no less effective than past standards, and in some cases are superior, resulting in restoration of Cook Inlet habitat.

Factor “(3) Disease and/or predation”

The proposed rule’s conclusion (19858) below is not based on supporting scientific information or substantive analyses:

*. . . the Cook Inlet beluga whale is in danger of extinction throughout all of its range because of . . . **disease and/or predation (further predation by killer whales can be shown to have a significant impact on survival)*** (emphasis added)

We provide comments on each of these two factors separately then combined. Regarding disease, the following additional conclusion in the proposed rule (19858) contradicts the conclusion above:

Despite the considerable pathology that has been done on belugas, nothing indicates that the occurrence of diseases or parasites has had a measurable impact on their survival and health. Therefore, diseases and parasites are not known to be factors that have led to the current status of the Cook Inlet beluga whale DPS.

Information in the draft conservation plan, status assessment, proposed rule, or other sources supports that conclusion. This supports the Service making a determination that an ESA listing based on disease is unwarranted at this time.

Regarding predation, the following two statements in the proposed rule (19858), taken together, also contradict the conclusion above that the whale is in danger of extinction because of predation:

The best available information does not allow us to accurately quantify the mortality level due to killer whale predation or its effect on the DPS.

*While disease and predation occur in the Cook Inlet beluga population and may affect reproduction and survival, **neither appears to be a likely contributor to the observed decline.*** (emphasis added)

The Service's statement that predation did not contribute to the decline in Cook Inlet stock of beluga is substantiated by analysis of killer whale movements and observed predation.

In contrast, the 2007 proposed rule (19858) makes a contradictory projection that "*the loss of more than one beluga whale annually could impede recovery, particularly **if total mortality due to predation** would be near the recruitment level in the DPS.*" (emphasis added) The recruitment level is projected to be 2 to 6 percent depending upon the model used, or 10-12 beluga whales. **There is no similar projection that the estimated take by killer whales of one beluga whale per year has increased or would be likely to increase ten-fold.**

Furthermore, it stands to reason that, if predation did not contribute to the decline caused by subsistence harvests that approximated roughly 50% of the population and was not subsequently found to be a factor for listing in 2000, then a significant increase in predation would have to occur for predation to contribute comparably to further declines and to the probability of extinction. Although the proposed rule asserts that "*further predation by killer whales can be shown to have a significant impact on survival,*" no scientific information or reasonable claim is provided to support that statement or to predict that past predation rates (estimated by the Service as one per year) will change or have changed since publication of the final determination that listing under ESA was not warranted in 2000.

Despite the lack of supporting information that predation is impeding recovery of the Cook Inlet stock of beluga whale, we recognize that predation by killer whales is a factor for which additional information is highly desirable. The State proposes significantly increased cooperative studies of predation and movements of killer whales be prioritized in the final Conservation Plan.

Regarding both disease and predation, the proposed rule concludes the following contradictory statement (19858) with no supporting substantive information or analyses that disease and predation are factors contributing to the probability of extinction:

However, the present low population abundance and the gregarious [no definition] nature of beluga whales predispose the population to significant consequences from disease and predation, which contributes to the probability of extinction, and, therefore to the proposed classification as endangered under the ESA.

The latter theoretical assertion does not constitute a finding based on best available scientific and commercial data. The same highly theoretical assertion, that "*significant consequences [could result] from disease and predation,*" could be applied to populations of any species at any level anywhere in the world. Given that diseases or parasites occur at levels significantly lower in the Cook Inlet stock than in other beluga stock around the world, the Service's application of this factor to justify an ESA classification is both arbitrary and unreasonable. Given that migrating killer whales that prey on beluga infrequently occur in Cook Inlet, the Service's application of this factor is likewise unsubstantiated and arbitrary.

Factor “(4) *The inadequacy of existing regulatory mechanisms*”

The lack of control of the unsustainable subsistence harvest that occurred prior to 1999 was the single contributing factor to the decline of the Cook Inlet stock of beluga whale. Subsequently, regulatory mechanisms contributed to stabilizing the population and continue to be effective in controlling the harvest. Thus, the decision in the final rule in 2000, that a listing is unwarranted, should be the same conclusion reached in the 2007 proposed rule. The State disagrees with the incongruous new conclusion in the 2007 proposed rule (19858-19859) that a lack of past controls endangers the whale:

. . . the Cook Inlet beluga whale is in danger of extinction throughout all of its range because of . . . the inadequacy of existing regulatory mechanisms (largely the past absence of regulations on subsistence harvests) (emphasis added)

This lack of existing regulatory mechanisms was not found to be a factor, so the Service’s 2000 determination was that an ESA listing was unwarranted; this likewise is not a factor today.

The proposed conclusion that Cook Inlet beluga whale is in danger of extinction is based upon the claim that the population is continuing to decline and that there is some statistical possibility that the population is too small to be sustainable. As explained in Chapter 1, the best available scientific and commercial data does not support this claim. Future harvests are controlled by existing regulatory mechanisms (co-management agreements) that were imposed to end prior unsustainably high harvests. These mechanisms are adequate to provide for rebuilding and prevent harvests from triggering further beluga declines. Additional mechanisms are discussed further as part of conservation efforts proposed in Chapter 3. Therefore, while the lack of regulatory mechanisms contributed to the decline of the Cook Inlet stock of beluga whale in the 1990s, effective regulatory mechanisms were implemented prior to publication of the 2000 rule. The stock is not currently in danger of extinction due to this factor.

Factor “(5) *Other natural or manmade factors affecting its continued existence*”

Although the State concurs that past subsistence hunting levels, in combination with natural mortality from stranding events and other causes, was unsustainable and significantly reduced the population prior to the 2000 rule, that rule concluded that an ESA listing is unwarranted. The State finds no substantive evidence to support the contradictory conclusion in the 2007 proposed rule (19859), which states:

. . . the Cook Inlet beluga whale is in danger of extinction throughout all of its range because of . . . other natural and manmade factors affecting its continued existence (effects of past subsistence removals) (emphasis added)

The Service discusses two components of this category: “*Impacts of Past Subsistence Harvest Efforts*” and “*Impacts of Stranding Events.*” Regarding the stranding events, we agree with the Service’s conclusion that “*mass stranding events are not believed to be a factor that has caused, or had a significant role in, the decline of the Cook Inlet beluga whale DPS.*” Because the unsustainable harvest was not curtailed until 1999, we concur that harvests contributed to the

decline. However, few belugas have been hunted since 1999, and we disagree that the harvest prior to 1999 “*must be considered as a factor in the proposed classification of the Cook Inlet beluga whale DPS as endangered.*” **This conclusion contradicts the conclusion reached in the 2000 final rule that the population was not endangered and that a listing was not warranted based on this factor or any other of the factors. That 2000 determination was based on the same information.** There are no scientific or commercial data supporting a change from that conclusion.

Prey Populations

During the public comment period, several individuals speculated that perhaps there is a lack of salmon to support a recovering beluga whale population. In the proposed rule and Status Review, the Service evaluates prey status and dismisses this as a potential factor. However, because this issue was raised we are providing the following summary of the status of Cook Inlet salmon stocks to further substantiate that this is not a factor:

Upper Cook Inlet Overall: The status of salmon stocks in Upper Cook Inlet (UCI) has been, and remains, very optimistic. Since the mid-1990s, Cook Inlet salmon management plans have become more tightly restrictive of commercial fishing and remain very restrictive compared to management in the 1980s. In the last 15 years, harvests ranged from 1.8 to 10.5 million fish, with a 10 year average of 3.7 million fish. The run strength of one species will affect how the Department manages harvests of another species. For example, if a poor run of Chinook salmon occurs in one year, harvests of other species, no matter their run strength, will be reduced due to conservation efforts.

Sockeye Salmon: Sockeye salmon are the most abundant species in UCI. Their harvests have ranged from 1.2 to 9.1 million (record year) in the last 15 years, with an average harvest of 3.2 million fish in the last 10 years. Runs were strong through the early 1990s until 1998. From 1998 to 2001, runs were weaker but generally sufficient to meet escapement goals. Since 2001, runs have rebounded. See Table below. Sockeye salmon runs, when compared decade by decade, have been stable and consistent since 1980.

Decade	Esc^a	Harvest	Total Run
1970-1979		1,136,304	1,675,929
1980-1989	1,181,250	4,360,213	5,997,673
1990-1999	1,208,899	3,812,910	5,566,874
2000-2006	1,634,007	3,107,936	5,481,415

Pink Salmon: Pink salmon runs in UCI are even-year dominant, with odd year average harvests typically less than 1/7th of even-year harvests. Assessments are based largely on commercial fish reports, recreational fishing success, and limited escapement monitoring. Pink salmon are counted as part of programs designed to enumerate Chinook, sockeye, and coho salmon. In general, pink salmon stocks in UCI are maintaining their even-year dominance and continue to return in numbers that reveal that there are no obvious problems with the stock. As an example, the 2006 pink salmon harvest of 404,000 was approximately 50,000 fish greater than the average from the previous five even-year harvests (10 year history).

Chum Salmon: Chum salmon production had a decade of mediocre runs beginning in the mid-1980s, in part due to impacts from fall flooding in the Susitna River Basin in 1986. Chum salmon stocks throughout Southcentral Alaska have mirrored Susitna River chum salmon production, both revealing reductions in abundance from the mid-1980s to the mid-1990s. Beginning in 1995, an improvement in chum salmon production was observed in many areas of Southcentral Alaska, including UCI. Chum salmon runs from 2000 to 2004 were much improved from those realized during the 1990s. The 2002 escapement counts of chum salmon in Susitna River tributary weirs were the highest ever observed for these systems, while the 2001 chum salmon escapement in the Little Susitna River was the second largest ever observed. Therefore, although there is a limited amount of information available for assessing chum salmon stocks in UCI, there are no obvious concerns at this time.

Coho Salmon: UCI's coho salmon stocks generally benefited from excellent production throughout most of the 1980s and early 1990s. However, coho salmon runs in 1997 and 1999 were viewed as mediocre. The 2000 run appeared to be much improved with the 2001 run being even stronger yet, and finally the 2002 run being exceptional, perhaps even a record run. Because coho salmon are strongly dominated by a 4-year cycle, the returns from the 1997 and 1999 brood years occurred primarily in 2001 and 2003. The 2003 run, while not exceptionally strong, still produced escapements nearly three times the level of the 1999 brood year. Since 1997, the drainage-wide coho salmon smolt emigrations have stabilized and coho salmon runs have also stabilized. Since 2000, Kenai River adult coho salmon runs have been considered good to excellent.

Chinook Salmon: UCI Chinook salmon stocks are relatively stable. The Kenai and Kasilof rivers contain both early and late-run Chinook salmon that support major sport fisheries. The Kenai River stocks are popular with anglers due to ease of access, commercial enterprises to support anglers, and large size of fish in the returns. Both returns are harvested to an unknown degree in a marine recreational fishery in Lower Cook Inlet and late-run fish are also harvested in marine commercial fisheries. Recent escapements for the Kenai stocks have met or exceeded spawning escapement needs over the past three years. Kasilof early-run Chinook salmon originate primarily in Crooked Creek and are supplemented by a Department hatchery program. Naturally produced Chinook salmon from this system have met or exceeded spawning escapement needs recently. Late-run Kasilof Chinook salmon support a developing sport fishery and are harvested in the mixed stock marine sport and commercial fisheries to an unknown degree. Ongoing Department research indicates that inriver sport fishery exploitation is relatively low in comparison to spawning population size. An escapement goal has not been determined for this stock due to insufficient data.

Conclusion

The Service's conclusion that the Cook Inlet stock of beluga whales is in danger of extinction throughout all of its range based on the above factors is not supported by the information described in the proposed rule (19858-19859) and in its supporting sources. **In fact, the information provided in the 2007 proposed rule and 2006 Status Review overwhelmingly supports reaching the opposite conclusion for each of these factors, consistent with the 2000**

conclusion that a listing is not warranted. The Service appears to be proposing to reverse its earlier determination that a listing is unwarranted. This new determination is based entirely on unsupported population modeling predictions of a continued decline (Chapter 1) and on unsubstantiated speculation of possible increases in “threats” described above. We find no basis for a conclusion that the above factors or the theoretical possibility that a combination of these factors currently places the Cook Inlet stock of beluga whales in danger of extinction. We urge the Service to reconsider these hypothetical and arbitrary conclusions and affirm its previous finding that a listing under ESA is not warranted at this time.

Chapter 3

Effectiveness of Ongoing and Planned Conservation Efforts by States or Local Entities

The State of Alaska (State) provides information in this chapter as requested by the proposed rule (19861), consistent with the Service's March 28, 2003, Policy for Evaluating Conservation Efforts (PECE) (68 FR 15100). The proposed rule (19859) described the policy by which the Service must consider efforts by the State, political subdivisions of the State, Native American tribes and organizations, local governments, and private organizations to protect species when considering an Endangered Species Act (ESA) listing:

The PECE provides guidance on evaluating current protective efforts identified in conservation agreements, conservation plans, management plans, or similar documents (developed by Federal agencies, state and local governments, tribal governments, businesses, organizations, and individuals) that have not yet been implemented or have been implemented but have not yet demonstrated effectiveness. The PECE establishes two basic criteria for evaluating current conservation efforts: (1) the certainty that the conservation efforts will be implemented, and (2) the certainty that the efforts will be effective. The PECE provides specific factors under these two basic criteria that direct the analysis of adequacy and efficacy of existing conservation efforts.

We address the ongoing and planned protective efforts by numerous entities according to the PECE criteria and their effectiveness in two categories below. We urge the National Marine Fisheries Service (Service) to cooperatively pursue implementation of multi-entity Cook Inlet beluga conservation efforts. Through these ongoing and planned efforts, the State, other agencies, non-government organizations, and public propose to cooperatively pursue and provide increased funding that enables the Service and other entities to continue implementation of important cooperative measures toward research and management of beluga whales and their habitat. This would provide greater benefit for the Cook Inlet stock of beluga whales than would be possible through a recovery plan following an ESA listing, particularly since no known factor is affecting current population numbers.

(1) Funding and Finalization of the Service's Planned Conservation Plan

Background

On May 31, 2000, (65 FR 121), the Service published a final determination that the Cook Inlet stock of beluga whales was depleted as defined in the Marine Mammal Protection Act (MMPA). In that final rule, the Service committed to completing a conservation plan:

A conservation plan will be prepared unless it would not promote the conservation of the stock. (34592)

NMFS will prepare a conservation plan as quickly as limited resources allow. Initial conservation efforts will not, however, be delayed until such a plan is final. (34595)
(emphasis added)

On April 6, 2004, (69 FR 66), the Service published a final rule governing the taking of Cook Inlet beluga whales by Alaska Natives for subsistence purposes and implemented stipulations agreed to in the record of hearing before Administrative Law Judge McKenna (March 29, 2002) and subsequent negotiations. One of the comments on the draft rule urged the Service to implement a conservation plan to address additional issues such as education and enforcement. The Service responded (17976):

NMFS also intends to develop a conservation plan for these whales. NMFS agrees that education and enforcement are necessary and intends for these elements to be part of a conservation plan.

On March 16, 2005, (70 FR 50), the Service published a notice of availability of a draft Conservation Plan (nearly five years after published intent to quickly prepare a plan). No coordination with the State occurred in the development of that plan. However, the Service acknowledged such coordination is needed (12854):

*The goals and objectives of the draft Plan can be achieved only if a long-term commitment is made to support the respective actions recommended herein. **The shared resources and cooperative involvement** of federal, state, and local governments, industry, academia, non-governmental organizations, Alaska Natives, and other invested individuals **will be required throughout the recovery period.** (emphasis added)*

The Department provided comments on May 16, 2005, to the Service to improve the Plan, including recommending additional studies and pointing out errors in the modeling and other calculations. The Department emphasized:

*“**the Plan should be revised and finalized promptly.** ...The possibility that CI belugas could be listed under the ESA further emphasizes the need to implement the Plan’s conservation strategy and proactively pursue actions to promote recovery.”*

Instead of coordinating with federal, state, and local governments and others to cooperatively complete and implement the conservation plan, on March 24, 2006, the Service published (71 FR 57) a Notice of request for information to prepare an updated status review “*to determine if this group of beluga whales should be listed as an endangered or threatened species.*” The Governor and Department signed a response on May 24, 2006, opposing a listing and urging additional scientific information be acquired. Between 2004 and 2007, the Service received repeated requests from the State and three municipal governments to be allowed opportunities to contribute to the plan and studies. In late June 2007, we learned that the Service was about to publish a final Plan. No opportunity had been provided for the State, other federal agencies, boroughs, universities, or others to engage in design and coordination of possible research since publication of the 2005 Draft Plan. We appreciate that the State was recently given an opportunity to provide additional input on the final Plan, and we believe the Service should prepare a coordinated plan with all affected entities as was visualized in the 2000 and 2005 rules. Cooperative efforts with other researchers, governments, and non-government entities would provide more financial and staffing support to acquire information on beluga whales, their habitat, and factors that contribute to their sustainability than the Service’s solo efforts.

Conservation Plan

To date, the following deficiencies are neither addressed in the 2005 Draft Conservation Plan nor in subsequent efforts by the Service:

- Need cooperation of all stakeholders and shared resources in the development of a Plan, including the State, federal agencies, boroughs, academia, and non-government entities.
- Need an implementation strategy; i.e., who will investigate what, monitor, and evaluate progress, identify sources of funding, develop cost-sharing and leveraging of funds.
- Need a multi-disciplinary team, such as the workshop that was held in March 1999, to discuss, develop, and prioritize objectives and studies to address the wide range of scientific information that is not available.
- Need to address education and enforcement (as promised above), hydrology and other physical changes occurring in the Inlet due to geologic and other physical parameters, and many other aspects missing.

The draft plan and ongoing research conducted by the Service appear to largely focus on the interests of its own scientists and those that have independent funding. Recent research on biological and physical characteristics of the Inlet was ignored in the 2007 proposed rule. This leads us to conclude that the Service is not considering the best available scientific and commercial data. No mention is made of recent research conducted in Upper Cook Inlet to identify individual whales to provide information on age structure and numbers or on fish forage studies.

Conclusion

The Service needs to immediately pursue cooperative effort with the government and non-government agencies to improve funding and other resources toward the completion of identified needs. We urge the above list be addressed and a cooperative effort completed for a final Plan as soon as possible. We also object to the following conclusion the Service published in the 2007 proposed rule:

We support all conservation efforts currently in effect; however, these efforts lack the certainty of implementation and effectiveness so as to have removed or reduced threats to Cook Inlet belugas. In developing our final listing determination, we will consider the best available information concerning these conservation efforts and any other protective efforts by states or local entities for which we have information (See description of PECE above).

We provide the following information that illustrates the State has implemented significant and effective conservation efforts.

(2) Ongoing and Planned Conservation Efforts by States and Local Entities

The following discussion of ongoing and planned conservation by states and local entities covers land and water habitat stewardship, management plans, regulatory mechanisms, fish and wildlife management, and regulatory mechanisms.

Habitat

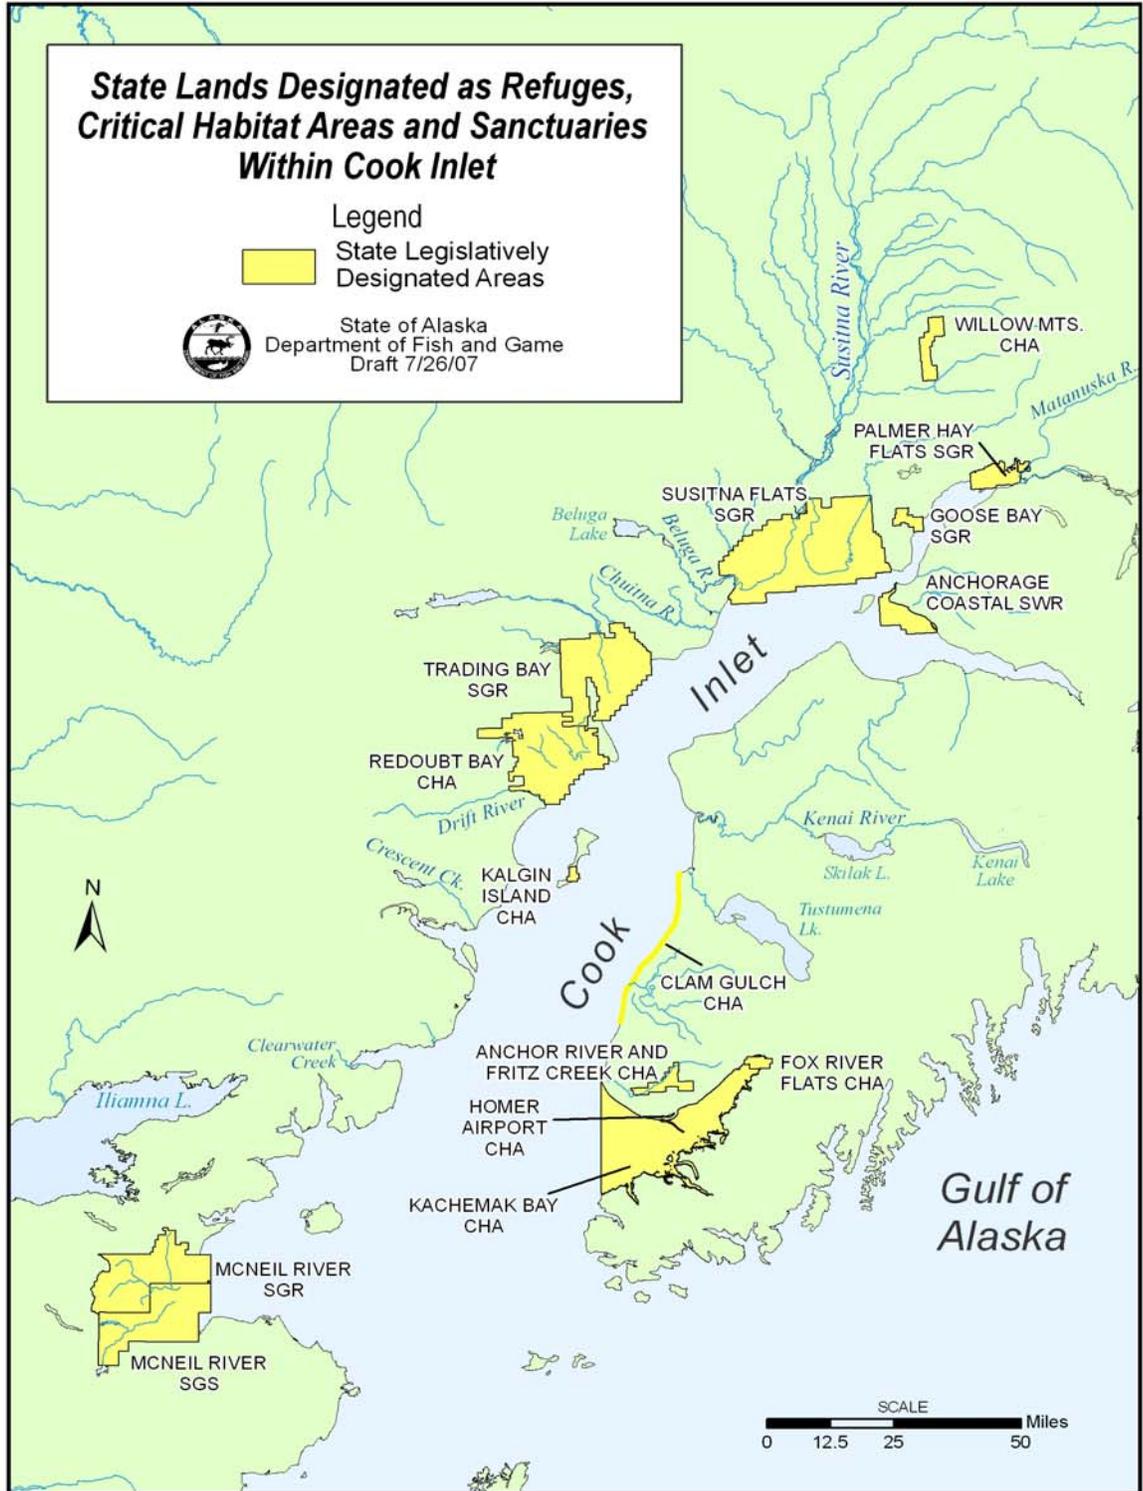

There is no scientific evidence to tie the decline of the Cook Inlet population of beluga whales to the destruction or modification of habitat (See further discussion of habitat “threats” in Chapter 2). During the 1994-1998 documented decline of beluga whales, there was no corresponding evidence of detrimental changes in habitat. The changes in habitat use by beluga whales appeared to relate largely to the decline in numbers, concentrating these social whales on selective habitat. The Wildlife Society recognized during the Alaska Center for the Environment suit (petition for the State to list beluga as endangered under State law) in 2003 that “*Physical habitat for Cook Inlet belugas is largely intact,*” and the Audubon Society noted no habitat problems for whales. No activities or developments have occurred since that time that would change the habitat within Cook Inlet.

Over 15 million acres of protected land in and around Cook Inlet helps to preserve good whale habitat. The habitat in Cook Inlet supports healthy populations of fish on which beluga whales prey, as evidenced by salmon returns to the river systems draining into Cook Inlet that continue to annually produce record numbers. These protected lands comprise State game refuges and critical habitats, special legislated management areas of the Upper Kenai and Recreational Rivers (Susitna), Chugach National Forest, Chugach State Park, and Katmai National Park and Preserve. (See Map in Overview) The State established through special legislative action 15 State game refuges and critical habitat areas, which provide protection for significant portions of the important beluga feeding areas in river mouths and in some areas out to three miles from Mean High Tide. Many of these State special land management areas were established nearly 30 years ago. (See Map and Table below)

All of these special land (and water) management areas have special management legislation limiting land use management activities, and most have detailed management plans in effect and that are effective in protecting habitat. In addition to land management plans, the State comprehensively regulates activities that occur throughout the Cook Inlet watershed that potentially affect water quality and quantity. Below are detailed examples of some of these management guidelines, regulations, and permit stipulations which are implemented by the Alaska Department of Environmental Conservation, Alaska Department of Natural Resources, and Alaska Department of Fish and Game as part of the State’s role in habitat protection measures.

ALASKA DEPARTMENT OF FISH AND GAME’S ROLE IN HABITAT PROTECTION

In addition to its many responsibilities for sustainability of fish and wildlife on all lands and waters in the State, the Alaska Department of Fish and Game (ADF&G) manages State lands designated as Refuges, Critical Habitat Areas and Sanctuaries within Cook Inlet.

Alaska Special Areas: Refuges, Sanctuaries and Critical Habitat Areas within the Cook Inlet Drainage, managed by ADF&G and the status of current management plans.

Name of Special Area	Date Established	Management Plan Required by Statute		Date of Management Plan
		Yes	No	
State Game Refuges				
Anchorage Coastal Wildlife Refuge	1971/1988	AS 16.20.031 (b)		1991
Goose Bay State Game Refuge	1975		No	
McNeil River State Game Refuge	1993		No	1995 (w/McNeil River State Game Sanctuary)
Palmer Hay Flats State Game Refuge	1975/1985		No	1986
				2002
Susitna Flats State Game Refuge	1976		No	1988
Trading Bay State Game Refuge	1976		No	1994 (w/Redoubt Bay Critical Habitat Area)
State Game Sanctuaries				
McNeil River State Game Sanctuary	1967/1993		No	1996 (w/McNeil River State Game Refuge)
Fish & Game Critical Habitat Areas				
Anchor River and Fritz Creek Critical Habitat Area	1985	AS 16.20.605 (d)		1989
Clam Gulch Critical Habitat Area	1976		No	
Fox River Flats Critical Habitat Area	1972		No	1993
Homer Airport Critical Habitat Area	1996		No	
Kachemak Bay Critical Habitat Area	1974		No	1993
Kalgin Island Critical Habitat Area	1972		No	
Redoubt Bay Critical Habitat Area	1989		No	1994 (w/Trading Bay State Game Refuge)
Willow Mountain Critical Habitat Area	1989	AS 16.20.620 (b)		

The ADF&G special area management plans are available at:
<http://www.wildlife.alaska.gov/index.cfm?adfg=refuge.main>

The ADF&G participates with other State agencies in **Oil Spill Contingency Plans**. The Alaska Department of Environmental Conservation (ADEC) requires all vessels transporting oil and hazardous substances within the State of Alaska to have a contingency plan in the event of a spill. Each operator is required to follow the ADEC format as described in 18 AAC 75, Article 4 which is located at the following link: http://www.dec.state.ak.us/spar/statutes_regs.htm#regs75

In addition to industry contingency plans, ADEC and other agencies, including ADF&G, formalized regional plans to ensure consistency. Cook Inlet has its own regional plan entitled 'The Cook Inlet Subarea Contingency Plan for oil and hazardous substance spills and releases'. This regional plan is located at : <http://www.akrrt.org/CIplan/CookInletSCP.shtml>. The industry contingency plans are a way that ADEC can ensure that the company is prepared and thinking in advance before they travel in Alaska waters. ADF&G reviews relevant industry plans with a focus on the protection of fish and wildlife.

Below is the “Unified Plan and Subarea Contingency Plan Description” of the regional plans, quoted from the Cook Inlet Subarea Contingency Plan:

UNIFIED PLAN & SUBAREA CONTINGENCY PLAN DESCRIPTIONS

The Cook Inlet Subarea Contingency Plan is a supplement to the *Alaska Federal/State Preparedness Plan for Response to Oil & Hazardous Substance Discharges/Releases* (commonly referred to as the Unified Plan). The Unified and the Subarea Contingency Plans represent a coordinated and cooperative effort by government agencies and were written jointly by the U.S. Coast Guard, the U.S. Environmental Protection Agency, and the Alaska Department of Environmental Conservation. The Oil Pollution Act of 1990 (OPA 90) requires the USCG and the USEPA to prepare oil spill response plans for the State of Alaska, which is designated as an entire planning region under federal guidelines. Alaska statute requires the ADEC to prepare a state-wide master plan addressing oil and hazardous substance discharges. The Unified Plan meets these federal (National Contingency Plan and OPA 90) requirements for regional and area planning, as well as State planning requirements.

OPA 90 requires the development of Area Contingency Plans for the inland and coastal zones of each federal region. For the Alaska region, there are three Coast Guard Captain of the Port zones and one inland zone. The three Captain of the Port zones are: 1) Southeast, which covers all of Southeast Alaska; 2) Prince William Sound, which covers the Prince William Sound area; and 3) Western Alaska, which includes the rest of coastal Alaska from Cook Inlet out the Aleutians and north to the Beaufort Sea and the Canadian border. The inland zone is subdivided into two sectors: 1) the North Slope oil production area and the Trans-Alaska Pipeline System (TAPS) and 2) all other areas inland from the coastal zones.

Alaska statute divides the state into ten regions for oil and hazardous substance spill planning and preparedness. The USCG and the USEPA joined with the ADEC to use these ten regions for area planning instead of the federal planning divisions since this would facilitate unified planning for the State of Alaska and prove more practical as well (for example, the huge COTP Western Alaska planning area is replaced by seven more manageable divisions). Because the State of Alaska is called a planning “region” under federal planning guidelines and to avoid confusion with the other federal term, “area contingency plans,” these ten subordinate planning regions of the State are called “subareas” in the context of the Unified Plan.

The Unified Plan contains information applicable to pollution response within the entire State of Alaska and meets the pollution response contingency planning requirements applicable to the federal and State governments. The plan provides broad policy guidance and describes the strategy for a coordinated federal, State and local response to a discharge, or substantial threat of discharge, of oil and/or a release of a hazardous substance within the boundaries of Alaska and its surrounding waters.

Under both federal and State law, the responsible party for an oil or hazardous substance incident is required to report the incident and mount a response effort to contain and cleanup the release. The federal and State governments mandate response plans for oil tank vessels and facilities that have stringent spill response requirements. If the responsible party fails to respond adequately or if no responsible party can be identified, then the federal and State governments will rely on the Unified Plan and the appropriate Subarea Contingency Plan for response protocols and guidance.

Whereas the Unified Plan contains general information for response efforts taking place anywhere in the State of Alaska, the Subarea Contingency Plan (SCP) concentrates on issues and provisions specific to its particular subarea. The Cook Inlet SCP focuses on the Cook Inlet region of the State. The boundaries of this subarea are described in the Background Section of this plan. The Cook Inlet SCP provides information specific to the area, including emergency response phone numbers, available response equipment and other resources, specific response guidelines, and information on hazardous substance presence and sensitive areas protection.

Alaska State statute mandates a public review of all new plans, an annual departmental review of these plans, and another public review whenever the plans are significantly revised. The ADEC offers a public review of these plans for a period of 30 to 60 days during which verbal and written comments are accepted. During this comment period, several public meetings are held at locations appropriate for the plan being reviewed. The federal government does not require public review for any of its plans, though the USCG and the USEPA, as part of the Alaska unified planning process, do cooperate with the State of Alaska and participate in the public review process.

Neither the federal nor the State government maintains a formal approval process for these plans. The Unified Plan and the SCPs are presented to the Alaska State Emergency Response Commission and the Alaska Regional Response Team (ARRT) for review and comment. The ARRT's concurrence is also part of the process for plan promulgation. Final promulgation of the plan is accomplished once the three plan holders – the USCG, the USEPA and the State of Alaska – sign the letter of promulgation.

ALASKA DEPARTMENT OF ENVIRONMENTAL CONSERVATION ROLE IN HABITAT PROTECTION

The following provides an overview of the Alaska Department of Environmental Conservation (ADEC) environmental monitoring and permitting in the Cook Inlet region.

The ADEC mission involves the permitting and authorization of actions relating to oil and gas development, oil spill prevention and response, pollutant discharges, and other activities affecting the waters of Cook Inlet. The agency's permitting and regulatory actions provide thorough habitat protections, and ADEC's water related permits and authorizations typically also involve the Environmental Protection Agency (EPA). Thus, our discussions include information and reference to EPA documents.

ADEC's responsibilities to address potential "threats" identified by the Service

The Service identified specific potential threats to Cook Inlet beluga whale habitat in the April 20, 2007, Federal Register notice of the proposed rule, including:

- Development of the Beluga Coal Mine
- Oil and gas exploration, development and production
- Oil spills
- Seafood processing
- Ship ballast
- Municipal wastewater treatment systems (Point Woronzoff and others)
- Urban runoff

Information provided by ADEC below addresses the above "proposed threats" in the following categories:

1. Oil spill prevention and response
2. Discharges to the waters of Cook Inlet
3. Ballast water discharges
4. Municipal wastewater discharges

5. Industrial wastewater discharges
6. Non-point source pollution and impaired waters that flow to Cook Inlet
7. Water Quality Monitoring and Assessment

1. Oil Spill Prevention and Response

ADEC's Spill Prevention and Response Division's activities are specifically focused on oil spill prevention and assurance of adequate oil spill response. ADEC focuses its resources on the consequences of an oil spill, rather than predicting the probability of an oil spill occurring. It is the specific responsibility of ADEC to ensure that the environmental consequences of a discharge can be mitigated to a degree protective of human health and the environment by requiring regulated operators to be prepared to respond to and clean up oil spills under typical environmental conditions.

In 2003, the Minerals Management Service (MMS) produced a final EIS for oil and gas lease sales (191 & 199) in the Cook Inlet Planning area. An oil spill risk assessment was produced as part of that effort which indicated the proposed action in the lease sale (oil and gas development) would result in a 2% chance of one or more platform-based spills, 16% to 17% chance of one or more pipeline spills, and 17% to 19% chance of one or more spills total.

The population viability analysis (PVA) noted by the Service in the *2006-16, Status Review and Extinction Assessment of Cook Inlet Belugas* (November 2006 Status Review) discussed "potential catastrophic events," which included oil or toxic substance spills, failure of key fish runs, ice entrapments or disease /parasite introductions; these added 10-15% to the probability of extinction. It was not clear from the report and the included references what oil spill data set (if any) was used to come up with the 10-15% factor. Below are the data from the ADEC Spills Database for spill information from 1996 through the present.

Summary of Spills to Cook Inlet, 1996-2006								
Calendar Year	Crude Oil		Hazardous Substances		Non-Crude Oil		Annual Total	
	count	Gallons	Count	gallons	count	gallons	count	gallons
1996	6	649	12	268	22	1,192	40	2,109
1997	12	81	8	110	30	10,729	50	10,920
1998	12	446	15	1,136	30	338	57	1,920
1999	31	1,529	10	425	37	542	78	2,496
2000	6	34	13	674	15	458	34	1,166
2001	11	508	17	247	22	492	50	1,247
2002	12	697	11	3,742	28	265	51	4,704
2003	6	186	18	778	23	78	47	1,042
2004	4	115	17	1,293	20	273	41	1,681
2005	6	91	17	1,649	31	714	54	2,454
2006	1	1	5	44	7	55	13	100
10-yr Total	107	4,337	143	10,366	265	15,136	515	29,839
10-yr Average	11	434	14	1,037	27	1,514	52	2,984

2. Discharges to the waters of Cook Inlet

Cook Inlet is a tidal estuary with a northeast to southwest orientation. It is roughly 180 miles long and averages 60 miles wide. Water depths are typically 100 to 200 feet but can be up to 500 feet in channels near the Forelands (near the middle of Cook Inlet). The flow of Cook Inlet water is generally to the southwest. Discharged substances that are dissolved or remain in suspension generally will be transported out of Cook Inlet and into the Gulf of Alaska within about ten months. The concentration of suspended particulate matter in the water column of lower Cook Inlet ranges from 1 – 50 parts per million (ppm).

Cook Inlet is a relatively large tidal estuary with a sizable tidal range. The turbulence associated with strong tidal currents as well as common winds results in the vertical mixing of the waters. A relatively large volume of water and a large variety of naturally occurring inorganic and organic substances are transported into Cook Inlet by the streams and rivers and by currents from the Gulf of Alaska. The amounts of individual substances discharged into the Inlet appear to be quite variable. Substances transported into Cook Inlet that remain in suspension or dissolved in the water column are dispersed by tidal currents and winds. Mean annual freshwater input to Cook Inlet exceeds 18.5 trillion gallons or an annual average of 50.6 million gallons per day (gpd). According to the Service, the principal sources of pollution in the marine environment are as follows:

- Discharges from industrial activities that do not enter municipal treatment systems
- Discharges from municipal wastewater treatment systems
- Run-off from urban areas, mining operations, airports, military sites and agricultural areas.
- Accidental Spills or discharges of petroleum and other products.

There is also an additional natural source of pollution, which the Service does not discuss in depth: the discharge of toxic pollutions from volcanic activity. Since 1980, three volcanic eruptions have occurred in the Cook Inlet basin, resulting in widespread ash distribution, mudflows, and corrosive precipitation, all of which may have had a short term affect on Cook Inlet water quality. The three most active volcanoes are Mt. Redoubt, Mt. Spur, and Mt. Augustine.

Permitted Discharges

The permitted discharges to Cook Inlet can be summarized as follows:

Municipal wastewater discharges – 42 million gpd
Industrial wastewater discharges due to oil and gas development –
 Production water – 7.36 million cubic meters = 5.33×10^6 gpd
 Drilling cuttings and wash water – 21,300 gpd
 Deck drainage – 25,100 gpd
 Sanitary wastes – 6,100 gpd

Domestic wastes – 6,900 gpd
Desalination wastes – 20,100 gpd
Uncontaminated ballast water – 79,200 gpd
Uncontaminated bilge water – 7,900 gpd
Muds, cuttings, cement at sea floor – 174,400gpd
Noncontact cooling water – 800,000 gpd
Fire control system test water – 8,800 gpd

Source: ODCE for Cook Inlet NPDES permit (converted to gallons from cubic meters)

Industrial waste discharges due to seafood processing facilities

Cook Inlet Fish Processors – 10,600,000 lbs per year.

Source: DEC estimates based on annual reports submitted for NPDES permit coverage.

Suspended Solids Discharged in Cook Inlet (per year)

The following data on suspended sediments provide perspective on the overall affect of industrial and municipal activity on Cook Inlet. Percentages in parentheses are the comparison of estimated annual industrial/municipal output to the total estimated annual output produced by the three rivers noted:

Suspended sediments - Knik, Matanuska & Susitna Rivers = 36,343,000 tonnes

Suspended solids discharged from municipalities = 2,030 tonnes (0.005%)

Suspended solids discharged from refineries = 30 tonnes (0.00008%)

Suspended solids discharged oil & gas drilling fluids /cuttings = 930 tonnes (0.002%)

Note: “tonnes” refers to metric tons

The Service noted in their October 2000 Environmental Impact Statement (EIS):

It seems likely that over time a qualitative effect from municipal, commercial and industrial activities in the Inlet on the water quality and substrate may affect Cook Inlet beluga whales. However, NMFS cannot, at this time, translate that qualitative likelihood into a statement of impact on the beluga whale population, or to the health of beluga whales in the Inlet.....Accordingly, NMFS concludes that the cumulative impacts of activities other than subsistence harvest are minimal.

Minerals Management Service studies of Cook Inlet water quality (1996) found that levels of hydrocarbons in the water column were generally low and often less than the method detection limit.

Since 1999, produced water discharges have increased at some oil and gas facilities, have decreased at some, and have stopped discharging altogether at others. **It should also be noted that no new development or production facilities will be authorized to discharge produced water under EPA’s proposed NPDES General Permit.**

3. Ballast Water Discharges

All vessels, foreign and domestic, trading in Cook Inlet waters are subject to mandatory federal ballast water exchange regulations (33 C.F.R. 151, Part D). These regulations require that the entire amount of ballast water loaded at the port of origin is exchanged with sea water during the voyage. The only exceptions in the regulations are for crude oil tankers in the coastwise trade and military vessels.

The sources for potential ballast water discharges to Cook Inlet waters are:

- Crude Oil Tankers
- Oil Product Tankers
- Liquefied Natural Gas (LNG) Ships
- Non-tank vessels

The only two companies that currently have approved State contingency plans to bring crude oil or oil products into Cook Inlet waters aboard tanker ships are Union Oil Company of California (Chevron) and Tesoro Alaska. These two companies could theoretically discharge ballast water from the lower 48 into Cook Inlet waters, but commercial considerations and cargo routing make this scenario unlikely. One facility near Drift River on the west side of Cook Inlet is permitted by the EPA to treat ballast water from the tanker trade in Cook Inlet. Very little discharge has occurred in recent years from this facility.

4. Municipal Wastewater Discharges

There are a number of municipal wastewater facilities that have the potential to ultimately discharge into Cook Inlet. There are also a number of smaller community systems and sewage outfalls that have the potential to ultimately discharge into Cook Inlet. The following wastewater treatment facilities (WWTF) are permitted under ADEC's wastewater regulations (18 AAC 72):

- Anchorage Point Woronzof Asplund WWTF
- Girdwood WWTF
- Settlers Bay Village Subdivision WWTF
- Eagle River WWTF
- Palmer WWTF
- Homer WWTF
- Kenai WWTF
- Soldotna WWTF

The Municipality of Anchorage operates the Point Woronzof sewage treatment plant under a National Pollutant Discharge Elimination System (NPDES) permit from the Environmental Protection Agency (EPA). This permit was originally issued in 1998 and was good for five years. The permit has been extended administratively since 2003, and the EPA is currently in the process of renewing the permit. This sewage treatment plant has approval from the EPA to discharge primary treated sewage through a Clean Water Act Section 301(h) waiver. This discharge is addressed in State water quality standards through a site-specific standard for the Pt. Woronzof facility.

The Service noted in their 2006 Status Review that municipal wastewater discharges may also include “*emerging pollutants of concern*” (EPOCs), which include endocrine disruptors, pharmaceuticals, personal care products, and prions. Recent national studies (outside of Alaska) by the Environmental Chemistry Branch, Environmental Sciences Division of the EPA showed unexpected levels of prescription drugs in sewage discharges. These emerging pollutants are being studied by the EPA, in order to determine specific regulatory authorities under which these pollutants would be tested for. The EPA and Alaska water quality standards do not currently regulate these “*emerging pollutants of concern*.” However, there is no evidence of high levels of discharge of “*emerging pollutants of concern*” in Cook Inlet or of any impact from these or any other pollutant on the Cook Inlet stock of beluga whales.

5. Industrial Wastewater Discharges

Oil and gas development has taken place in Cook Inlet since 1957, and at present there are over 200 oil wells in production and three production plants on the shores of Cook Inlet. The majority of industrial wastewater discharges permitted by EPA and ADEC are associated with oil and gas facilities located in or adjacent to Cook Inlet. There are also a number of seafood processors who have discharges permitted by EPA and ADEC. The following oil and gas facilities are on platforms located in or immediately adjacent to Cook Inlet:

- Chevron Nikiski Refinery
- Tesoro Alaska Kenai Refinery
- Unocal Swanson River
- Unocal Trading Bay Production Facility
- Unocal Anna Platform
- Unocal Baker Platform
- Unocal Bruce Platform
- Unocal Dillon Platform
- Unocal King Salmon Platform
- Unocal Dolly Varden Platform
- Marathon Oil Spark Platform
- Phillips Tyonek Platform A
- Marathon Oil Spur Platform
- Unocal Granite Point Platform
- Unocal Grayling Platform
- Unocal Monopod Platform
- Unocal Steelhead Platform
- Forest Oil Osprey Platform
- Cook Inlet Pipeline Co. Drift River Facility

Much of the Cook Inlet oil and gas activity is permitted through the EPA’s NPDES General Permit for oil and gas operations in Cook Inlet. The reissued general permit is also proposed to cover additional oil and gas leases that are located in nearby federal waters adjacent to Cape Douglas and the Barren Islands. The January 2006 *EPA Ocean Discharge Criteria Evaluation for the Cook Inlet NPDES Permit* report provides critical baseline information and updates

regarding water quality issues in Cook Inlet. The NPDES permit also includes data on existing approved mixing zones, the parameters in the mixing zones, as well as effluent water quality data. ADEC issued a Certificate of Reasonable Assurance (401 Certification) for this EPA NPDES permit on May 18, 2007, and this ADEC document will be released with the final NPDES permit.

6. Non-Point Source Pollution and Impaired Waters that Flow to Cook Inlet

There are a number of waters that flow into Cook Inlet that are considered impaired according to water quality regulations. The bulk of the impaired waters are listed due to non-point source pollution, including fecal coliform pollution associated with urban run-off or land development. The following waters adjacent to Cook Inlet are in the impaired water category:

<u>Anchorage</u>	<u>Wasilla</u>
Campbell Creek	Cottonwood Creek
Campbell Lake	
Chester Creek	<u>Palmer</u>
Fish Creek	Matanuska River
Furrow Creek	
Lake Hood/Spenard Lake	<u>Eagle River</u>
Jewel Lake	Eagle River
Little Campbell Creek	
Little Rabbit Creek	<u>Kenai</u>
Little Survival Creek	Kenai River
Ship Creek	
University Lake	
Westchester Lagoon	
Cheney Lake	

Urban growth and development has the potential to increase the percentage of impervious surface coverage in the Cook Inlet drainage. The percentage of impervious surface coverage of lands can affect the ability to control non-point source pollution from reaching Cook Inlet. Site specific studies have been performed on the Kenai Peninsula and on the Chester Creek watershed in Anchorage regarding this issue, but a lack of data for surrounding areas and a poor match with nationwide urban stormwater data make it difficult to make any predictions on the effects of future development on non-point source discharges. There is no scientific information showing that any appreciable impacts on the Cook Inlet stock of beluga whale is likely from nonpoint source pollution.

The Eagle River Flats in Fort Richardson, near Anchorage are also listed as impaired due to the presence of white phosphorus due to sustained military munitions activity in the area. This impairment is not new, and there is no scientific information indicating any appreciable effect on the Cook Inlet stock of beluga whales.

Nonpoint source pollution in Cook Inlet has not significantly increased since 2000 and is subject to increasing storm water discharge control requirements.

7. Water Quality Monitoring and Assessment

The Clean Water Act (CWA) mandates that each state develop a program to monitor the quality of surface and groundwaters and prepare a report describing the water quality. The U.S. Environmental Protection Agency (EPA) then compiles and summarizes the information from all the state reports and sends this information to Congress. The process for developing information on the quality of the nation's water resources is contained in several sections of the CWA: Section 305(b) requires that the quality of all waterbodies be characterized; Section 303(d) requires that states list any waterbodies that do not meet water quality standards.

As part of these efforts, ADEC has been monitoring water quality levels for the Kenai River, which ultimately empties into Cook Inlet. In past years, hydrocarbon levels have been exceeded slightly for 1 to 2 days during peak river use in summer, attributable in part to the use of sport fishing boats with outboard engines. In the 2006 Integrated Report, the Kenai River was placed on the Category 5/Section 303(d) list of impaired waters for non-attainment of the petroleum hydrocarbons water quality standard. As part of this process, ADEC and other involved agencies will be developing a restoration plan for improving the water quality in the Kenai River. Regulatory actions have already been implemented in 2007 to reduce hydrocarbons from outboards on the Kenai River. In addition, ADEC also has water quality records of Kenai Peninsula streams, which includes data on temperature. Temperature of water bodies can have an affect on the fish reproduction, timing of fish runs and fish mortality.

In 2006, ADEC published a report *Alaska Monitoring and Assessment Program: The Condition of Southcentral Alaska's Bays and Estuaries Technical Report and Statistical Summary*. This report provides a regional survey of water quality, sediment and biological indicators. These can provide a baseline of the ecological condition of this region, which includes many sampling locations within Cook Inlet and surrounding areas. Metals, petroleum hydrocarbons, and other general water quality parameters were analyzed that may be useful in assessing potential impacts to Cook Inlet's beluga whales. No scientific information available to date demonstrates that water quality is having any appreciable affect on the Cook Inlet stock of beluga whales.

Other Potential Developments Affecting Cook Inlet

Plans were announced in 2006 regarding development of Cook Inlet's Beluga coal fields as part of the Chuitna Coal Project. This project is located 45 miles west of Anchorage and involves coal to liquids fuel technology. This project is currently in the preliminary permitting stages. In June 2006, the EPA released the Draft Scoping Document for a Supplemental Environmental Impact Statement (EIS). The effects of this proposed development will become clearer once the EIS process is completed and plan are solidified in anticipation of applying for a permits. There may be issues related to noise from construction, loading conveyors, and vessel traffic, that are not regulated by ADEC, but these impacts can be limited by other agencies under either direct authorities or through the ACMP program..

Fish Tissue Monitoring

ADEC has been involved in a fish tissue monitoring project, which included some sampling of fish in Cook Inlet. ADEC's Fish Tissue Testing Program was put into place to determine the safety of Alaskan seafood, including subsistence species. These fish tissue test results include fish that are eaten by beluga whales in Cook Inlet. Results from the program so far include tissue samples from 119 fish from Cook Inlet, with the following species sampled: pacific cod (6), pacific halibut (28), lingcod (18), walleye pollock (11), yelloweye rockfish (7), salmon (26), and spiny dogfish (1). Tissue samples were analyzed for arsenic, cadmium, chromium, nickel, lead, selenium, methylmercury, and total mercury. In almost every case, statewide average and median metal concentrations were higher than those for Cook Inlet. The only notable exception was yelloweye rockfish tissue, which had higher methylmercury and total mercury concentrations than the statewide average. Even in yelloweye rockfish, the higher methylmercury and total mercury concentrations were not significantly higher than the statewide average.

ADEC Summary

The EPA's March 2006 Environmental Assessment of Reissuance of NPDES Permit for Oil and Gas Exploration, Development and Production Facilities located in State and Federal Waters in Cook Inlet, Alaska noted the following in its discussion of threatened and endangered species:

Long-term minor adverse effects on threatened and endangered species would be expected from discharge from new sources with the implementation of the draft NPDES permit under Alternative 1 (Note: This was EPA's final permit preferred alternative). The effects discussed(in the analysis] apply equally to threatened and endangered species, i.e., the threatened and endangered species that occur in Cook Inlet are not likely to inhabit waters close to the permitted activities and are therefore unlikely to be affected by discharges from oil and gas facilities. Furthermore, with respect to water quality, the Final Environmental Impact Statement (FEIS) for the Cook Inlet Planning Area oil and gas lease sales concluded that the "potential effects from either or both sales would not cause any overall measurable degradation to Cook Inlet water quality" (MMS 2003).

Similar conclusions can be made for other discharges to Cook Inlet. All discharges are subject to increasingly more stringent regulatory controls, significantly greater than those in place during the 1970s and 1980s when the majority of the development in Cook Inlet occurred. There is no scientific evidence showing any impacts on the Cook Inlet stock of beluga whales from water pollutants has occurred in the past and such impacts are even more unlikely under the more stringent standards now in place.

ALASKA DEPARTMENT OF NATURAL RESOURCES ROLE IN HABITAT PROTECTION

The following is a summary of the Alaska Department of Natural Resources' (DNR) regulatory authorities and a compilation of mitigation measures that pertain to beluga whales. This information is organized by administrative division, providing contact information.

OFFICE OF PROJECT MANAGEMENT & PERMITTING

The Office of Project Management and Permitting (OPMP) houses the Large Project Permitting section (LPP) and is tasked with responsibility and authority of administering Alaska's Coastal Management Program (ACMP).

Large Project Permitting

The LPP functions are found under AS 38.05.020(b)(9), which requires the Commissioner of DNR to coordinate permitting activities for all large resource development projects, and AS 27.05.010(b) which requires DNR to be the lead agency for permitting all large mine projects. LPP's goal is to ensure that all aspects of a large project are considered during a single review and approval process. The LPP is currently coordinating the permitting of mining, oil and gas, and transportation projects, including the Chuitna Coal Project in the Cook Inlet watershed.

LPP assigns a project manager to serve as the primary contact for a large project. The project manager coordinates the permitting activities of the state team assigned to work on the project. The Large Project Team is an interagency group, coordinated by LPP, to work cooperatively with project applicants and operators, federal resource agencies, and the Alaskan public to ensure that projects are designed, operated, and reclaimed in a manner consistent with the public interest. The project manager's primary responsibility is to ensure a coordinated process with minimum duplicity of efforts. This often involves tailoring the process to fit specific project needs.

The goal of the State's Large Project Team is to coordinate the timing and completion of the numerous permits. The team reviews all the complex technical documents generated during the process and provides coordinated comments. The team also coordinates stakeholder involvement and provides a single point of contact for the public. The team provides the public, agencies, and the applicant the opportunity to view the project as a whole.

The requirement for the federal authorizations usually triggers the requirement for an Environmental Impact Statement (EIS) pursuant to the National Environmental Policy Act (NEPA). The State usually participates as a cooperating agency in the EIS process, and the team endeavors to dovetail the State's permitting process with the EIS process. For example, during the Pogo Mine process, the public Draft EIS included drafts of all the major State permits. This gave the public the opportunity to see how the State's management decisions could be implemented on the ground and enabled them to comment on the project as a whole.

The Large Project Team also coordinates, to the extent possible, with local governments. For example, the team has been working closely with the City and Borough of Juneau throughout the permitting and EIS process for the Kensington Mine. The City's Conditional Use Permits are critical authorizations for the mine and may place additional stipulations on the project.

Alaska Coastal Management Program

The ACMP facilitates the implementation of various beluga whale conservation measures at several distinct levels during land and resource planning processes, as well as at the level of individual project planning and development. Below is a bulleted list of these responsibilities of the Office of Project Management and Permitting (OPMP):

1. Pre-application assistance & meetings. The OPMP is tasked with arranging and scheduling meetings between a prospective developer and the agency personnel that would be reviewing, critiquing, and writing permits to authorize a given development project. These meetings provide an invaluable opportunity for industry to meet face-to-face with agency scientists and resource managers. Oftentimes beluga issues are brought to an applicant's attention at these meetings. Thus, when a developer is made aware of potential wildlife conflicts and/or potential adverse impacts of their planned project ahead of time, the finalized plan of operation or facility footprint is substantially modified before permit applications are even filed. At these meetings, prospective applicants are made aware, if they are not already, of the need to design and site facilities so as to be consistent with statewide standards and district enforceable policies. Applicants are also made aware of the (oftentimes) many distinct special-interest groups that need to be "kept in the loop" for the planning/approval process. This list typically includes subsistence oversight groups, Native Tribes, Native Councils, commercial or recreational fishing interests, environmental groups, etc.
2. Requirements/Standards for what review materials need be submitted. Applicants need to provide OPMP and review participants with:
 - (1) completed Coastal Project Questionnaire;
 - (2) map(s) identifying the location of the project and adjacent facilities, diagrams, technical data, and other relevant material;
 - (3) description of any man-made structures or natural features that are at or near the project site;
 - (4) an evaluation of how the proposed project is consistent with the state standards and with any applicable district enforceable policies, sufficient to support the consistency certification;

These materials are of paramount importance in assisting agency personnel as well as the public review a given project for its potential impacts to coastal uses and resources. It is partially with these materials that a review participant can suggest alternative measures that will improve a proposed development project. Similarly, the requirement imposed by the coastal consistency review process for federal agencies to submit consistency evaluations along with draft plans (for example, OCS oil & gas leasing plans) enables a more thorough review and comment adjudication.

3. Public process/ public review. Most State and federal agency authorizations (permits) go through both public and agency review processes often coordinated by the OPMP. This fulfills many agencies responsibility for posting/distributing public notice. It also provides a key tool wherein US Fish and Wildlife Service, Alaska Department of Fish and Game, State agency biologists, the public, and the coastal district can raise attention to scientific, social, and/or environmental concerns relative to beluga habitats or beluga

population dynamics or health of a given proposed plan or project. Plan adoption and/or individual authorizations for a given project must, through the coastal consistency review process that is adjudicated by the OPMP, be deemed consistent with ACMP standards before said permit is issued or plan is adopted. Oftentimes the OPMP will have to negotiate and include specific alternative measures designed to minimize potentially adverse impacts to belugas into a project description before it can be deemed consistent and permits can be written.

4. Program Plans and District Enforceable Policies. The OPMP assists coastal districts develop and adopt Program Plans and District Enforceable Policies. According to statewide standards of the ACMP, as well as the local enforceable policies, the ACMP review process functions as a tool for adding restrictions or mitigating measures (in the form of Alternative Measures) to the authorizations that are issued.
5. Resolve Conflicts. The OPMP works to act as a facilitator to attempt to resolve conflicts among the resource agencies, an affected coastal resource district, &/or an applicant--before, during, or after a project is permitted.
6. Other. Where the specific aspects of an activity that would otherwise be subject to authorization by the ADEC are not subject to that department's authorization because the activity is either a federal activity or is located on federal land or the OCS, the ADEC can review, comment on, and/or add alternative measures to said activity *only* through the ACMP. Thus, the ACMP provides a very valuable role in its being the only venue for the State to comment on, allow, disallow or make modifications to certain federal actions or private activities located on federal land or the OCS. This leverage is of paramount importance in areas that also happen to be crucially important as habitat for belugas.
7. Statewide Standards. Specific statewide standards and enforceable policies that have bearing on conserving belugas and beluga habitat include:
 - ▶ **11 AAC 112.230. Energy facilities.** (a)(1) The siting and approval of major energy facilities by districts and state agencies must be based, to the extent practicable, to minimize adverse environmental and social effects while satisfying industrial requirements;
 - ▶ **11 AAC 112.230. Energy facilities.** (a)(2) The siting and approval of major energy facilities ... must be based, to the extent practicable, to be compatible with existing and subsequent adjacent uses and projected community needs;
 - ▶ **11 AAC 112.230. Energy facilities.** (a)(11) The siting and approval of major energy facilities ... must ... minimize the probability, along shipping routes, of spills or other forms of contamination that would affect fishing grounds, spawning grounds, & other biologically productive or vulnerable habitats, including marine mammal rookeries and hauling out grounds...
 - ▶ **11 AAC 112.230. Energy facilities.** (a)(12) The siting and approval of major energy facilities ... must ... allow for the free passage and movement of fish and wildlife with due consideration for historic migratory patterns;

- ▶ **11 AAC 112.230. Energy facilities.** (a)(13) Major energy facilities should be sited so that areas of particular ... environmental, or cultural value ... will be protected;
- ▶ **11 AAC 112.270. Subsistence.** (a) A project within a subsistence use area designated by the department or under 11 AAC 114.250(g) must avoid or minimize impacts to subsistence uses of coastal resources. (b) For a project within a subsistence use area designated under 11 AAC 114.250(g), the applicant shall submit an analysis or evaluation of reasonably foreseeable adverse impacts of the project on subsistence use as part of (1) a consistency review packet submitted under 11 AAC 110.215; and (2) a consistency evaluation under 15 C.F.R. 930.39, 15 C.F.R. 930.58, or 15 C.F.R. 930.76.
- ▶ **11 AAC 112.300. Habitats.** (b) (1) Offshore areas must be managed to avoid, minimize, or mitigate significant adverse impacts to competing uses such as commercial, recreational, or subsistence fishing, to the extent that those uses are determined to be in competition with the proposed use;
- ▶ **11 AAC 112.300. Habitats.** (b) (2)(B) Estuaries must be managed to avoid, minimize, or mitigate significant adverse impacts to competing uses such as commercial, recreational, or subsistence fishing, to the extent that those uses are determined to be in competition with the proposed use;
- ▶ **11 AAC 112.300. Habitats.** (b) (5)(A) Rocky islands and sea cliffs must be managed to avoid, minimize, or mitigate significant adverse impacts to habitat used by coastal species (5) rocky islands and sea cliffs must be managed to avoid, minimize, or mitigate significant adverse impacts to habitat used by coastal species;
- ▶ **11 AAC 112.300. Habitats.** (b) (6)(C) barrier islands and lagoons must be managed to avoid, minimize, or mitigate significant adverse impacts from activities that would decrease the use of barrier islands by coastal species, including polar bears and nesting birds;

DIVISION OF OIL AND GAS

Background: oil and gas areawide leasing

The purpose of areawide leasing is to provide an established time each year that the State will offer for lease all available acreage within five geographical regions. In 1999 the Division of Oil and Gas prepared a best interest finding for the Cook Inlet region. The finding is in effect for 10 years. The Cook Inlet Areawide finding covers an area of approximately 4.2 million acres.

Prior to a sale, DNR issues a request for new information that has become available since the most recent finding for that sale area was written. Agencies and the public are given a comment period to provide new information. Based on information received, DNR will determine whether there is "substantial new information" that justifies a supplement to the finding. A supplement to the finding or a "decision of no substantial new information" is issued approximately 90 days prior to the sale. The final best interest finding for the Cook Inlet Areawide was issued on

January 20, 1999, and supplemented on May 20, 2000, February 18, 2004, and again on February 21, 2007.

The Best Interest Finding and Supplements are available on the Division's website:
<http://www.dog.dnr.state.ak.us/oil/products/publications/cookinlet/cookinlet.htm>

In 1999, the Service identified 126 tracts in Cook Inlet that are, in the Service's opinion, important beluga whale habitat. DNR worked with the Service to develop mitigation measures that would allow oil and gas exploration, development and production to go forward, while still protecting beluga habitat. Nonetheless, as a result of litigation, leasing of the tracts identified by the Service was stayed by the Superior Court in *Cook Inlet Keeper v Alaska*, Case No. 3AN-99-3343CI.

A July 28, 2000, Superior Court Order affirmed the Cook Inlet Areawide 1999 Oil and Gas Lease Sale Final Best Interest Finding and Consistency Determination in all parts, exclusive of the Cook Inlet beluga whale population issues relative to 126 tracts that were remanded for additional consideration. The Service made recommendations that allowed for a resolution of the beluga tracts.

The Service recommendations addressed all Cook Inlet lease sale tracts. They segregated the tracts into three categories: Category One contained all tracts in Upper Cook Inlet that have the highest observed use by beluga whales, including nearshore areas along the west and north shoreline, Knik Arm, and Turnagain Arm; Category Two contained all other nearshore tracts which have also been identified as concentration areas during summer periods; and Category Three contained all other sales tracts.

NMFS recommended:

- oil and gas exploration and development (permanent or temporary) should not occur in Category One tracts, unless it occurs on upland tracts;
- leasing of Category Two tracts be conditioned such that no permanent surface entry or structures occurs (other than upland areas), and that all temporary activities and structures (e.g. exploration drilling) occur only between November 1 and April 1 of each year; and
- no specific conditions for Category Three tracts.

To address these recommendations, the following "Mitigation Measures" were added to the Best Interest Finding under the "Facilities and Structures" section:

32. No permanent offshore structures will be allowed, and temporary structures will be allowed only between November 1 and April 1 of each year, within the following tracts: 126, 127, 129 thru 132, 161, 162, 175, 177, 211, 218, 257, 301, 302, 373, 376, 377, and 384.

33. No offshore facilities will be allowed, both temporary and permanent, within the following tracts: 320 thru 334, 391 thru 409, 462, 464 thru 475, 485, 486, 493, 494, 497, 498, 522, 524 thru 537, 540, 541, 544, 547 thru 552, 559, 575 thru 577, 579, 581, 582, 585, 586, 590, 593, 594, 598, 616 thru 618, 620 thru 623, 627, 655 thru 658, and 662.

The Cook Inlet Areawide tract map is available online at:

http://www.dog.dnr.state.ak.us/oil/products/publications/cookinlet/ciaw2007/CI2007_Tractmap_Med_4%20Mb.pdf

In addition, the Service recommended that a Lessee Advisory concerning beluga whales be included in the Cook Inlet Areawide Oil and Gas Lease Sale Best Interest Finding, as quoted below.

9. Endangered and Threatened Species: The Lessee is advised that the Endangered Species Act of 1973 (ESA), as amended (16 U.S.C. 1531 et seq.) protects the following endangered or threatened species and candidate species for listing that may occur in the lease sale area:

<u>Common Name</u>	<u>ESA Status</u>
a. Fin whale	Endangered
b. Sei whale	Endangered
c. Steller sea lion (western stock)	Endangered
d. Beluga whale (Cook Inlet stock)	Candidate
e. Steller's eider (Alaska breeding population)	Threatened

The National Oceanic and Atmospheric Administration, National Marine Fisheries Service (NMFS) is the agency responsible for management of marine mammals with the exception of sea otters, polar bears and Pacific walrus that, in addition to migratory birds, are managed by the U.S. Fish and Wildlife Service (USFWS).

NMFS and the USFWS have requested that the Lessee be further advised that:

- Offshore seismic operations may result in the taking¹ of marine mammals. Such taking is prohibited by the Federal Marine Mammal Protection Act (MMPA), unless otherwise authorized. The incidental taking of marine mammals may be authorized under the MMPA, and each operator should discuss this matter with NMFS well in advance of any geophysical survey activity.
- The USFWS has determined that oil and gas exploration and development activities within three miles of the eastern shore of Cook Inlet, from Clam Gulch to the southern bounds of the lease sale area, is likely to adversely affect² Steller's eiders. Each operator is advised to consult with the USFWS well in advance of any activities in this area.

NMFS, USFWS, and ADF&G will continue annual monitoring efforts to further delineate the presence and distribution of species administered under the ESA and

¹ Under the MMPA, "take" means: harass, hunt, capture, collect, or kill attempt to harass, hunt, capture, or kill any marine mammal.

² Under the ESA, "take" means: to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct. "Harm" is further defined by USFWS to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns including breeding, feeding, or sheltering. "Harass" is further defined by FWS as intentional or negligent actions that create the likelihood of injury to listed species to such extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding, or sheltering.

MMPA. The Lessee is advised to annually acquire updated information from these agencies.

In addition, lessees are required to implement oil spill prevention, control, and countermeasures plans and the use of explosives is restricted in marine waters:

Mitigation Measure 1

Oil and hazardous substance pollution control: In addition to addressing the prevention, detection, and cleanup of releases of oil, contingency plans (C-Plans) for oil and gas extraction operations should include, but not be limited to, methods for detecting, responding to, and controlling blowouts; the location and identification of oil spill cleanup equipment; the location and availability of suitable alternative drilling equipment; and a plan of operations to mobilize and drill a relief well.

Lessee Advisory 1

The use of explosives for seismic activities with a velocity of greater than 3,000 feet per second in marine waters is prohibited.

Permitting and Compliance Program

The Permitting and Compliance Unit within the Division of Oil and Gas approves Plans of Operation for activities on State oil and gas leases, geophysical exploration permits, and miscellaneous land use permits on all State lands and waters. Bonding requirements must be fulfilled prior to any activity. Geophysical exploration activities are governed by 11 AAC 96.

Plan of Operations applications are reviewed for compliance with stipulations and mitigation measures in the oil and gas lease. Most proposed activities in the coastal zone must meet the standards of the Alaska Coastal Management Program and go through a public comment period.

The Permitting and Compliance Unit also performs field inspections to see that operations are conducted in conformance with the terms and conditions contained in the approval.

DIVISION OF MINING, LAND AND WATER

The Division of Mining, Land and Water (DMLW) has the responsibility and authority to manage all commercial (excluding oil and gas exploration and development activities) and recreational use of State land and waters and resources on those lands. In Cook Inlet, Turnagain Arm, and Knik Arm, this includes the tidelands and submerged lands that have not been conveyed to the cities or boroughs. Although DMLW does not manage the navigable use of the marine waters, it does authorize docks, buoys, fiber optic cables, dredging, and other uses of the tide and submerged land.

The DMLW authority primarily comes from AS 38.05, AS 41.23, and AS 46.15. This DMLW authority is overlapped by the authority of the Division of Oil and Gas for oil and gas leasing and development and that of the Joint Pipeline Office for common carrier pipeline right of ways.

Land Management Plans

The DMLW is responsible for writing area plans and management plans for State lands. This is done through a public process to create the policy and guidance of how the lands will be managed. This process includes consideration of tide and submerged lands, sensitive habitats, and development needs.

Area plans provide management guidance to authorizations issued by DNR on the protection of fish and wildlife resources through two components: areawide policies and specific management units occupying State uplands or tidelands.

Areawide policies: The Kenai Area Plan applies ACMP requirements derived from District Plans as well as statewide ACMP standards for the protection of sensitive fish and wildlife, including tideland areas. In this case, the Kenai District Plan requires that “*uses and activities within or adjacent to coastal waters shall not interfere with migration or feeding of whales.*” In addition, the Kenai Area Plan has the following mitigation policy, quoted below:

C. Mitigation. The following mitigation policy will apply where coastal district mitigation policies are not in effect for state lands.

1. When authorizing the use or development of state lands, the Department of Natural Resources and the Department of Fish and Game will evaluate the requirements of the activity or development and the benefits or impacts it may have to habitat when determining stipulations or measures needed to protect fish and wildlife or their habitats. The costs of mitigation relative to the benefits to be gained will be considered in the implementation of this policy.
2. All land use activities should be conducted with appropriate planning and implementation to avoid or minimize adverse effects on fish and wildlife or their habitats.
3. The department will enforce stipulations and measures, and will require the responsible party to remedy any significant damage to fish and wildlife or their habitats that may occur as a direct result of the party's failure to comply with applicable law, regulations, or the conditions of the permit or lease.
4. When determining appropriate stipulations and measures, the department will apply, in order of priority, the following steps. Mitigation requirements listed in other guidelines in this plan will also follow these steps.
 - a. Avoid anticipated, significant adverse effects on fish and wildlife or their habitats through siting, timing, or other management options (see Table 2.3 for timing guidelines)

- b. When significant adverse effects cannot be avoided by design, siting, timing, or other management options, the adverse effect of the use or development will be minimized.
- c. If significant loss of fish and wildlife habitat occurs, the loss will be rectified, to the extent feasible and prudent, by repairing, rehabilitating, or restoring the affected area to a functional state.
- d. DNR will consider requiring replacement or enhancement of fish and wildlife habitat when steps "a" through "c" cannot avoid substantial and irreversible loss of habitat. The Department of Fish and Game will clearly identify the species affected, the need for replacement or enhancement, and the suggested method for addressing the impact. Replacement or enhancement of similar habitats of the affected species in the same region is preferable. DNR will consider only those replacement and enhancement techniques that have either been proven to be, or are likely to be, effective and that will result in a benefit to the species impacted by the development.

Replacement or enhancement will only be required by DNR if it is determined to be in the best interest of the state either through the original Best Interest Finding process (AS 38.05.0335(e)) or through the permit review process. Replacement may include structural solutions such as creating spawning or rearing ponds for salmon, creating wetlands for waterfowl, or non-structural measures such as research or management of the species affected, legislative or administrative allocation of lands to a long-term level of habitat protection that is sufficiently greater than that which they would have otherwise received, or other management practices to increase habitat productivity.

Management units: The Turnagain Arm area is affected by the Kenai area plan and the Turnagain Arm management plan. The management intent for the tidelands from the management plan requires that these areas be retained in public ownership and managed for multiple uses, with a management emphasis of protecting recreational opportunities, the high scenic values of the Seward Highway corridor, and the protection of fish and wildlife habitat. The Kenai area plan identifies specific management requirements for tidelands within the Kenai Peninsula Borough in units 503 and 504. Both of these management units recognizes the importance of this area as a summer feeding area for Beluga whales and co-designate the tidelands as Habitat/Public Recreation. DNR must ensure, when issuing authorizations within Turnagain Arm, that sensitive habitats and fish/wildlife resources are maintained and, specifically, that the summer feeding area for Beluga whales are protected.

The Knik Arm area is not affected by an area plan. The Willow Subbasin, one of our first area plans, did not provide management intent or include specific management units for tidelands and submerged lands. This plan is currently being updated and will include this information when finalized. The revision process should take over a year and once completed, DNR will have specific management requirements for this resource which will provide direction for the issuance of subsequent authorizations.

Land Use Authorizations

DMLW authorizes land uses through permits, leases, rights of way, sales, and other authorizations. All DMLW authorizations are granted in accordance with the plans or, if they deviate from the plan, a public process is conducted to allow an exception or amend the plan. These authorizations are to assure that any operation is conducted in a manner that will prevent unreasonable degradation of the land and water resources and that the management requirements of area plans are met. In addition, since these marine areas are in the coastal zone, authorizations must first be deemed consistent with the Alaska Coastal Management Program plans and enforceable policies. DMLW will consider these plans and place any restrictions or mitigating measures in the authorizations through stipulations to protect the social or environmental concerns, inclusive of critical habitats.

DMLW's statutes and regulations are fairly general and are non-specific regarding beluga related issues. For example, the authority for attaching stipulations to DMLW permits is 11 AAC 96.040 (b) "*Each permit is subject to any provisions the department determines necessary to assure compliance with this chapter, to minimize conflicts with other uses, to minimize environmental impacts, or otherwise to be in the interests of the state.*" Leasing statutes and regulations also do not have any specific language except under AS 38.05.073 where commercial recreation leasing plans **must consider fish, wildlife** and other resources affected by the specific recreation facilities. However, an overriding statute in AS 38.04.005(b) requires that DNR must consider natural resources and conditions present on the land and seek to **minimize the adverse effect of private settlement on wildlife, fishery**, mineral, timber, and other significant resources of the land when determining how to provide for maximum use of State land consistent with the public interest.

For surface coal activities authorized by DMLW, a fish and wildlife protection plan, under 11 AAC 90.081, must be developed to **prevent or minimize disturbance and adverse impacts on fish, wildlife, and related environmental values** to protect, enhance, or mitigate effects to threatened, endangered, or important species if they can reasonably be expected to be affected by the proposed activities. The plan must include protective measures to be used during active mining operations and enhancement measures to be used during the reclamation and post-mining phases to develop aquatic and/or terrestrial habitats.

Most all other authorizations go through public and agency review process where Alaska Department of Fish and Game, OHMP, ADEC, EPA, Army Corps of Engineers, or the U.S. Fish and Wildlife Service can bring attention to any environmental concerns about a proposed project. DMLW will then address those concerns when creating the authorization. If agencies identify specific habitat or species that would be directly impacted by the proposed project, DMLW will work with those agencies to develop mitigating measures that would be required of the permit applicant.

At present, most authorizations in this area contain no specific stipulations regarding belugas, but many contain some form of hazardous substance stipulations, such as these quoted below:

- a) *All fuel, petroleum and other toxic agents stored or utilized by the processing vessel must not be transferred while moored and must be contained or confined in a manner which would prevent any spillage from entering the adjacent water body.*
- b) *The permittee shall take all reasonable precautions to prevent water pollution, erosion, or sediment on or in the vicinity of the permitted area. This includes, ensuring that the discharge of wastewater from the processing vessel shall be from a USCG-certified Type II [Marine Sanitation Devis] MSD and that the anchor systems shall be free of oil, grease and other pollutants.*
- c) *Discharges of waste petroleum products or liquid wastes of any kind, not authorized under the EPA discharge permit AK-00586-8, is prohibited.*
- d) *The Permittee is responsible for contacting the Department of Environmental Conservation (DEC) office for plan review and approval of their methods for sewage disposal and potable water.*
- e) *The buoy and running lines shall be sited so as to avoid interference with navigation for the purpose of public use and enjoyment, existing fisheries, or other authorized uses.*

OFFICE OF HABITAT MANAGEMENT AND PERMITTING

Under its Title 41 authorities, the Office of Habitat Management and Permitting (OHMP) reviews proposed development activities to evaluate effects of that activity on fish passage and fish habitat. As needed, OHMP adds conditions to its permits to eliminate or minimize these effects. Maintaining fish passage and fish habitat helps protect fish populations, some of which may be utilized by beluga whales. OHMP biologists also review, comment, and suggest stipulations for the Division of Oil and Gas lease sales and ACMP reviews.

STATE PIPELINE COORDINATOR'S OFFICE

The State Pipeline Coordinator's Office (SPCO) administers pipelines authorized under AS 38.35, the Right-of-Way Leasing Act. Typically, right-of-way leases will contain conditions and stipulations to protect fish and wildlife resources; examples of each are included below. In addition, construction and operation activities associated with common carrier pipelines on the North Slope are governed by the ACMP process, which is described above.

Example of Lease Conditions (quoted below):

11. Mitigative, Preventive, and Abatement Activities Required (a) The LESSEE will, at its own expense in accordance with the terms of this LEASE and in the manner set forth in the appropriate plans and programs developed pursuant to Stipulation 2.5.1:
 - (1) maintain the LEASEHOLD and PIPELINE SYSTEM in good repair;
 - (2) promptly repair or remedy any damage to the LEASEHOLD; and
 - (3) promptly compensate for any damage to or destruction of property for which the LESSEE is liable, resulting from damage to or destruction of the LEASEHOLD or PIPELINE SYSTEM.
- (b) The LESSEE shall prevent or, if the procedure, activity, event or condition already exists or has occurred, shall abate, as completely as practicable, using the BEST PRACTICABLE TECHNOLOGY AVAILABLE and in the manner set forth in the appropriate

plans and programs developed pursuant to Stipulation 2.5.1, any physical or mechanical procedure, activity, event or condition:

- (1) that is susceptible to prevention or abatement;
- (2) that arises out of, or could adversely affect, PIPELINE activities; and
- (3) that causes or threatens to cause

(A) a hazard to the safety of workers or to the public health or safety (including but not limited to personal injury or loss of life with respect to any PERSON or PERSONS); or

(B) immediate, serious, or irreparable harm or damage to the environment (including but not limited to soil, sediments, water and air quality, areas of vegetation, fish or other wildlife populations or their habitats, or any other natural resource).

(c) Unless clearly inapplicable, the requirements and prohibitions imposed upon the LESSEE by this LEASE (including the Stipulations thereto) are also imposed upon the LESSEE's employees, and the LESSEE's agents and contractors and the employees of each of them. The LESSEE shall ensure compliance with this LEASE (including the Stipulations thereto) by its employees and by its agents and contractors, and the employees of each of them.

13. Orders and Notices (a) The COMMISSIONER may issue any order necessary to enforce or implement any provision of this LEASE. Before delivery of any such order, the COMMISSIONER shall confer with LESSEE, if practicable to do so, regarding the required action or actions included in the order. Any such order shall state in detail what is demanded of LESSEE and the reasons and basis for such demand.....

(i) In coordination with the FERC, and consistent with applicable State and Federal law, the COMMISSIONER may, by written order, require the LESSEE to make such modification of the PIPELINE SYSTEM as the COMMISSIONER determines is necessary to:

- (1) protect or maintain stability of the foundation and other earth materials;
- (2) protect or maintain integrity of the PIPELINE SYSTEM;

(3) control or prevent significant damage to the environment (including but not limited to soil, sediments, water and air quality, areas of vegetation, fish or other wildlife populations or their habitats, or any other natural resource); or

(4) remove hazards to public health and safety, including the activities of the LESSEE, the LESSEE's agents, and contractors, and the employees of each of them.

15. Temporary Suspension (a) The COMMISSIONER may, consistent with applicable State and Federal law, order the temporary suspension of any or all PIPELINE activities, if

(1) an immediate temporary suspension of the activity or the activities is necessary to protect:

(A) public health or safety (including but not limited to personal injury or loss of life with respect to any PERSON or PERSONS); or

(B) the environment from immediate, serious or irreparable harm or damage (including, but not limited to harm or damage to soil, sediments, water and air quality, areas of vegetation, fish or other wildlife population or their habitats, or any other natural resource); or

Additional Example of Lease Stipulations (quoted below):

2.5 DESIGN CRITERIA, Plans and Programs

2.5.1 The LESSEE shall submit DESIGN CRITERIA to the COMMISSIONER. The LESSEE shall also submit comprehensive plans and/or programs (including schedules where appropriate) which shall include but not be limited to the following:

(25) Human/Carnivore Interaction

Plan Purpose and Objective: This plan will provide design criteria and basic methodologies for various pipeline activities that will be used to minimize human/carnivore interactions and will describe the measures to be employed to provide employees with adequate training and knowledge to deal with the potential dangers associated with interactions between humans and bears and other carnivores.

Performance Standard: The LESSEE shall minimize the occurrence of human-carnivore interactions during pre-construction, CONSTRUCTION, operation and maintenance, and TERMINATION activities by taking measures to prevent interactions between humans and carnivores. This plan shall contain personnel safety guidelines developed in consultation with the Alaska Department of Fish and Game (hereinafter "ADF&G").

2.15.5.2 Zones of Restricted Activities

2.15.5.2.1 Activities of the LESSEE in connection with CONSTRUCTION, operation, maintenance and TERMINATION of the PIPELINE SYSTEM in key fish and wildlife areas and in specific areas where threatened or endangered species of animals are found may be restricted by the COMMISSIONER during periods of fish and wildlife breeding, nesting, spawning, lambing and calving activity, over-wintering, and during major migrations of fish and wildlife. The COMMISSIONER shall provide the LESSEE written notice of such restrictive action. At least annually, and as far in advance of such restrictions as is possible, the COMMISSIONER shall furnish the LESSEE an updated list of those areas where such actions may be required, together with anticipated dates of restriction.

2.15.5.3 Big Game Movements

2.15.5.3.1 The LESSEE shall design, construct and maintain both the buried and above ground sections of the PIPELINE so as to assure free passage and movement of big game animals.

DIVISION OF FORESTRY

The Alaska Forest Resources and Practices Act (FRPA, AS 41.17) governs how timber harvesting, reforestation, and timber access occur on state, private, and municipal land. Forest management standards on federal land must also meet or exceed the standards for State land established by the Act. The FRPA was originally adopted in 1978. Major revisions were adopted in 1990 to address riparian management on private land, enhance notification procedures for timber operations, reorganize the Board of Forestry, and establish enforcement procedures. Additional changes to the stream classification system and riparian management standards were adopted in 1999 for Region I (coastal Alaska) and in 2003 for Region III (interior Alaska). Review of the standards for Region II (southcentral Alaska) is in progress.

Purpose. The FRPA balances economic concerns for the timber industry with water quality and habitat protection needs. It protects fish habitat and water quality, ensures prompt reforestation,

and helps the timber and fishing industries provide long-term jobs. This framework provides certainty and credibility for landowners, operators, and the public.

Key provisions. The FRPA:

- Establishes a process for landowners to notify the State before beginning commercial timber operations. This is not a permit process. Tight timeframes are set for agency review of notifications, and timber operations can proceed if the agencies do not respond within the set time frame.
- Sets standards for forest management along waterbodies, including buffers, and provides flexibility to harvest valuable trees within buffers when it can be done without harming fish habitat or water quality. Harvest within buffers requires agency approval. Buffers are tailored to the conditions in each region.
- Sets standards to prevent erosion from roads and harvest areas into waterbodies.
- Requires reforestation except where land will be converted to another use, or where the harvest area is significantly composed of dead or dying trees.
- Provides one-stop shopping for forest operation compliance with state and federal clean water and coastal management standards.
- Authorizes DOF to enforce the Act through directives, stop work orders, and citations for violations.

Best management practices (BMPs). Regulations adopted under 11 AAC 95 also establish BMPs for road construction and maintenance, and for timber harvesting. These standards are designed to prevent adverse impacts to fish habitat and water quality from timber operations.

Regions and applicability. Alaska is divided into three forest practices regions. Region I covers coastal forests from Southeast Alaska through Prince William Sound, the eastern Kenai Peninsula, the Kodiak Archipelago, and parts of the Alaska Peninsula. Region II is the boreal forest south of the Alaska Range. Region III is the boreal forest in Interior Alaska.

The FRPA applies to commercial timber operations on forestland, including harvesting, road building, site preparation, thinning, and slash treatment operations on forestland. Operations must comply with the FRPA if they are larger than 10 acres in Region I or larger than 40 acres in Region II. In Region III, it applies to operations larger than 40 acres for forest landowners that own more than 160 acres in total. All commercial harvest operations that encompass or border surface waters or a riparian area also must comply with the Act, regardless of their size.

SUMMARY OF REGULATORY MECHANISM

Existing regulatory mechanisms for the protection of the Cook Inlet stock of beluga whales and its habitat are extensive. There is no scientific evidence that a failure of any of these mechanisms, other than the former lack of a mechanism to restrict harvest, contributed to the decline of the Cook Inlet stock of beluga whales. Likewise, there are no scientific data showing any of the increasingly more stringent mechanisms for conservation of the Cook Inlet stock of beluga or its habitat are inadequate for recovery of the stock from prior unsustainable harvest.

Chapter 4

Identification of Critical Habitat or Essential Physical and Biological Features for this Species

As defined in the Endangered Species Act (ESA), critical habitat includes geographic areas and features essential to the conservation of the species, which may require special management consideration or protection. This includes specific areas outside of the area presently occupied where such areas are essential to the conservation of the species. Therefore, in order to identify critical habitat or essential physical elements for the Cook Inlet stock of beluga whales, the Service must be able to identify their geographic range and features important to conservation. The 2007 proposed rule (19857) concludes “*the present range of the Cook Inlet beluga is limited to Cook Inlet waters north of a line from Cape Douglas to Cape Elizabeth.*” However, published literature documents beluga sightings throughout the Gulf of Alaska. The literature also addresses speculation of why the more recent sightings are primarily in upper and middle Cook Inlet. Previous tagging studies in Cook Inlet were very limited and the resulting movements may be limited because beluga whales tend to move in family units. With no current tagging studies and no studies across several family units, the information acquired on the geographic range of the Cook Inlet stock of beluga whales is of limited value in assessing which areas should be considered for critical habitat designation.

In our upcoming discussions with the National Marine Fisheries Service (Service), we will urge that a final conservation plan include additional research on whale movements. For example, we will propose additional tagging of the Bristol Bay stock of beluga whales that may occasionally disperse into the Gulf of Alaska based on current genetics analysis of the Cook Inlet whales. (See Chapters 1 and 3) We will also urge that acoustics research be carefully designed with multidisciplinary experts to identify beluga whale, orca, prey, and other species movements throughout the Inlet.

As described for the development of a final conservation plan (Chapter 3), the State of Alaska (State) urges that the Service establish a multidisciplinary team to convene a series of workshops whose goals are to identify studies that can address specific objectives for the acquisition of need information on the beluga whales and the essential features of their habitat. As written in the draft conservation plan, the Service places a heavy influence on the upper part of Cook Inlet without explaining why other areas are not important. It may be possible that belugas are affected by factors in the lower part of the Inlet, or even in the Gulf of Alaska, particularly in winter when they are feeding in deeper waters for resident fish and shellfish. Other federal agencies have considerable information on federal fisheries research and monitoring in the lower Inlet and outer waters that should be added to the data base. We recommend that the proposed habitat “GIS” coverage be expanded to include bathymetric information, hydrology, prey distribution, and geologic information for the whole inlet.

An evaluation of habitat must also consider that the geology and hydrology of Cook Inlet is dynamic. For example, the 1964 earth quake caused the Chickaloon Bay and other parts of Turnagain arm to rapidly subside but some areas appear to be slowly returning to its pre-quake

levels. The delta created by the sediments from the Susitna River is ever-changing in its form and water channels. These are all factors that could affect the physical habitat of the Cook Inlet stock of beluga whales. Many agencies and institutions have considerable data which need to be evaluated in addition to prey abundance, movements, and other factors. We conclude that the Service has not fully evaluated available scientific and commercial data and urge that a comprehensive and coordinated effort be implemented before any determinations of critical habitat are made. In Chapter 5, we also provide substantial information as requested in the 2007 proposed rule (19861) on the economic attributes within the Cook Inlet region that could be impacted by critical habitat designation. As part of that evaluation, pursuant to section 4(b)(2) of the ESA, we urge the Secretary of Commerce to consider the economic impacts of such a designation in Cook Inlet and exclude areas, which provide significant economic benefit to the State and region, from designation of critical habitat because there is no scientific information that such exclusion will result in extinction of the species.

Chapter 5

Examples of Economic or Other Relevant Impacts of Designation of Critical Habitat

The State of Alaska, as trustee of the fish and wildlife within Alaska's boundaries, shares with the Service the responsibility for continued survival and recovery of the Cook Inlet stock of beluga whales. Therefore, the beluga population's survival and recovery is of paramount importance to the State. As discussed in Chapters 1-3, the State finds no basis for the Service's proposal to list the Cook Inlet beluga whale DPS as endangered and concludes that existing regulatory mechanisms and management actions adequately assure that the habitat will be protected. Consequently, the State concludes that no critical habitat or primary constituent elements (PCE) should be designated. This conclusion is based on the lack of scientific or commercial information and analyses regarding the status of the population that would support an ESA listing. This conclusion is not based on the potential significant economic or other impacts that would accompany an ESA listing and critical habitat designation.

If, despite the lack of scientific basis, the Service lists the Cook Inlet stock of beluga whale under ESA, then the Service will evaluate critical habitat and PCE for possible designation. Chapter 5 provides the State's comments requested by the Service in the 2007 proposed rule (19861) related to the fifth ESA listing factor: "(5) *Economic or other relevant impacts of designation of critical habitat.*" This chapter also addresses the following statement and solicitation for information (19861):

*The ESA directs the Secretary of Commerce to consider the economic impact of designating critical habitat, and under section 4(b)(2) **the Secretary may exclude any area from such designation if the benefits of exclusion outweigh those of inclusion, provided that the exclusion will not result in the extinction of the species.** We are considering proposal of critical habitat for the Cook Inlet beluga whale in a separate rulemaking. To assist us with that rulemaking, **we specifically request information on the economic attributes within the Cook Inlet region that could be impacted by critical habitat designation, as well as identification of the PCEs or "essential features" of this habitat and to what extent those features may require special management considerations or protection.*** (emphasis added)

Information regarding existing regulatory mechanisms which protect critical habitat and essential physical or biological features for the Cook Inlet stock of beluga whales are addressed in Chapter 3. Thus, this chapter addresses the current economic attributes of the Cook Inlet region and beyond that could be impacted by an ESA listing, the required ESA Section 7 consultation, and a critical habitat designation. If the Cook Inlet stock of beluga whale is listed as an endangered species under ESA, Section 9 "*prohibits certain activities that directly or indirectly affect*" the species by any individual, organization, or agency subject to United States jurisdiction (19860). The activities discussed below are examples of activities that directly or indirectly could be interpreted to affect the Cook Inlet stock of beluga whales.

Range of public activities potentially impacted:

Before identifying potential economic impacts or attributes affected by an ESA listing, the range of activities potentially involved must be identified. Under Section 7 of ESA, all federal agencies are required to consult with the Service to ensure that activities which the agencies authorize, fund, or carry out are not likely to jeopardize the continued existence of the species or to destroy or adversely modify critical habitat. Examples include “. . . permits and authorizations relating to coastal development (including seismic exploration), toxic waste and other pollutant discharges, Federal fishery management plans, and cooperative agreements for subsistence harvest.” The proposed rule (19858) specifically references the following proposed developments and ongoing activities that are planned and permitted within Cook Inlet that could be impacted by a critical habitat designation:

(1) Major expansion to the Port of Anchorage, which requires filling more than 135 acres of intertidal and subtidal habitat, with increased in-water noise from pile driving, dredging, and expanded port operations; (2) Port McKenzie expansion as a commercial port facility directly across a narrow portion of upper Cook Inlet from the Port of Anchorage; (3) the proposed Knik Arm Bridge, which would increase in-water noise with both construction and operational activities and would occupy a portion of upper Cook Inlet that is presently undeveloped and provides important beluga feeding and other habitats; and (4) construction and operation of a large coal mine and marine terminal along the west side of upper Cook Inlet, near the Native Village of Tyonek. Ongoing activities that may impact this habitat include: (1) continued oil and gas exploration, development, and production; and (2) industrial activities that discharge or accidentally spill pollutants (e.g., petroleum, seafood processing, ship ballast, municipal wastewater treatment systems, runoff from urban, mining, and agricultural areas).

The types of developments and activities impacted by a critical habitat designation may also include vessel traffic for subsistence, recreational, and commercial fishing on the rivers and in marine waters throughout the Cook Inlet watershed. Activities may also include military operations, state regulated timber and mining activities, air transportation into the airports and for access to remote sites, state management of fish species that are prey to beluga, shipping, cruise ships, and many other routine activities, perhaps reaching as far as upland wetland fill permits necessary for home construction.

The majority of the State's populous throughout the State depends upon the shipping into and transportation out of Anchorage, and over half of the state's population reside near or engage in the activities described above associated with the Cook Inlet watershed. **Identifying which activities could be affected by a critical habitat designation and then estimating the economic impact of additional permitting requirements and stipulations will require more comprehensive evaluation than is possible during this public comment period. Consequently, the State comments provide only examples and discuss the economics of select activities related to possible critical habitat designation. More detailed economic analysis will be necessary prior to any designation of critical habitat.**

Geographic range of habitat or PCE potentially designated:

A review of “*Habitat areas identified for CI beluga whales*” in Figure 5 of the 2005 draft Conservation Plan includes all of Cook Inlet (including Kachemak Bay) out to the Barrier Islands as the known range. (Other publications document beluga sightings on the south side of the Alaska Peninsula, around the coast of Kodiak Island, throughout Prince Williams Sound, and areas in the Gulf of Alaska) Based on the petition to list and testimony by the petitioners at public hearings, the Service will be pressured to list all of Cook Inlet as critical habitat and to list certain fish species as PCE. Although the Service recognizes that these activities and current habitat conditions did not contribute to the decline in the Cook Inlet stock of beluga whale, **an ESA listing may lead to a critical habitat designation. If a critical habitat designation includes the entire marine waters of Cook Inlet, it may also affect many activities occurring on land that potentially use fresh waters that run into the Inlet, thus affect the economies of all the communities surrounding the Inlet.** The potential economic impact of the beluga whale listing and critical habitat designation is difficult to assess and will largely depend on how a Beluga Recovery Plan is written, the nature and extent of the critical habitat designated, how the critical habitat designation impacts Section 7 consultation on existing permitting, and other regulatory mechanisms. This is difficult to predict since there is no identifiable cause for the recovery of the Cook Inlet stock of beluga whales being slower than was predicted by the Service.

Commercial activities or attributes within Cook Inlet watershed:

OIL AND GAS

Modern exploration in Cook Inlet began in 1955 when Richfield Oil Corporation began exploration on the Kenai Peninsula in the Swanson River area. Oil was discovered on July 23, 1957. This discovery began an oil rush in south central Alaska. Shortly after the Swanson River discovery, Standard Oil Company of California and Richfield formed a joint venture to explore for oil. Additional wells were drilled in the Swanson River area, and more onshore leases were taken on both sides of Cook Inlet. Several other oil companies moved in to participate in leasing and drilling activities on the Kenai Peninsula. By 1959, 187,000 barrels of crude oil were produced annually. The State’s first competitive sale was held December 10, 1959, bringing the State more than \$4 million in bonus bids. By 1960, further development of the Swanson River and Soldotna Creek Units raised annual oil production to 600,000 barrels. Five other Cook Inlet fields began production between 1965 and 1972. In 1962, Pan American Petroleum Corporation discovered the first offshore oil in Cook Inlet. This led to extensive exploration throughout the Cook Inlet region in the 1960s and 1970s. Chevron opened a refinery in 1963. The Tesoro refinery began operating in 1969. Cook Inlet production peaked at 83 million barrels per year in 1970 and declined to 7 million barrels per year in 2005.

More recently, the West McArthur River field began production in 1993 and Redoubt oil field in 2002. All Cook Inlet oil is currently shipped to the Tesoro refinery at Nikiski on the Kenai Peninsula. Oil from fields on the west side of Cook Inlet is transported by pipeline to the Drift River terminal then transported to Nikiski. Oil from the eastside fields is shipped by pipeline directly to the refinery. By year-end 2005, the Cook Inlet tallied more than 1.3 billion barrels of cumulative oil production, including about 11 million barrels of natural gas liquids.

Cook Inlet gas production began as a by-product of Swanson River oil development. As more oil and gas fields were discovered, nearby markets for the gas were developed in Anchorage and Kenai to supply space heat and electricity generation. In 1968 Unocal launched the ammonia-urea plant at Nikiski to take advantage of the abundance of cheap stranded natural gas. This plant was acquired in 2000 by Agrium Inc. of Calgary, Alberta. In 1969, Phillips and Marathon began operating the liquid natural gas (LNG) plant, also located at Nikiski.

LNG exports to Japan accounted for about a third of total Cook Inlet gas production. Total industrial use of Cook Inlet gas, including LNG exports, fertilizer manufacture, and oil field operations, has remained fairly constant at about 75 percent of total consumption since 1990. Cook Inlet natural gas production has remained relatively stable at an average of 203 Bcf per year from 2001 to 2005. In recent years, the steady increase in residential and commercial demand for space heating and electric power generation has been balanced by declines in oil field operations and reduced fertilizer production.

The history of Swanson River gas production differs from other Cook Inlet fields. Initially, gas was imported from other fields and injected into Swanson River to enhance oil recovery. In 1992, the operator began to “blow-down” the reservoir. In recent years, the Swanson River field became a major net gas producer in Cook Inlet and, since 2005, has been transformed into a federally approved gas storage facility with approximately 2 Bcf of annual storage capacity. The State approved two gas storage facilities in Cook Inlet in depleted reservoirs at Pretty Creek and Kenai Field, which contribute 0.7 and 6 Bcf, respectively, annual storage capacity to the Cook Inlet gas pipeline system.

The Cook Inlet sale area encompasses approximately 4 million acres divided into 815 tracts ranging in gross area from 640 to 5,760 acres. The sale area consists of state-owned uplands and tide and submerged lands lying between the cities of Houston to the north, Homer to the south, the Chugach and Kenai mountain ranges to the east, the Aleutian Range to the west, and within Cook Inlet. In this year’s sale (May 24, 2007), 45 tracts were sold (213,120 acres) bringing in \$2.3 million in bonus bids.

Cook Inlet oil production peaked at 230,000 barrels per day in 1970 and declined to 19,500 barrels per day in 2005. Oil production in Cook Inlet is expected to continue beyond 2025, including oil production from the Beaver Creek field and other non-state lands. Oil and gas exploration drilling since 2000 in Cook Inlet is driven by strong demand and rising prices for both oil and gas, coupled with decline in production from existing fields.

In summary, the majority of developments along the Inlet occurred in the 1960s and 1970s. While the population in the communities has grown, the additional oil and gas facilities and related developments throughout the Inlet have occurred at a slow pace and have been tightly regulated by the responsible state and federal agencies. This development occurred without impact to the beluga population. In 2001, gas reserves in south central Alaska were estimated to be at about a nine year supply. Over the past 6 years, there have been about 30 exploratory wells drilled in Cook Inlet compared with approximately 226 exploratory wells from 1955 through 1999. (See Table below) That approximate rate of exploration can be expected to increase over the next two decades, as the limitations on gas supply in Southcentral Alaska become more

severe. There are, however, no indications of a rapid and imminent increase in exploration. The economic value of that activity, in drilling alone, is roughly \$200 - \$300 million. Support services such as roads and facilities and other indirect and induced economic benefits to the area (primarily to the Kenai Peninsula) add much more.

Table: Oil and gas exploration wells and gas fields discoveries in Cook Inlet, 1955-2003.

Time Period	Number of exploratory wells drilled	Number of gas fields discovered	Success ratio (%)	Estimated ultimate recovery (Bcf)
1955-60	17	5	29.4	2,603.50
1961-65	42	9	21.4	3,575.23
1966-70	85	6	7.1	1,814.86
1971-75	29	1	3.4	10.86
1976-80	14	1	7.1	8.19
1981-85	13	0	0	0
1986-90	5	0	0	0
1991-95	11	2	18.2	139.78
1996-00	10	3	30.0	151.72
2001-03	14	1	7.1	100.00 (?)
Total	240	28	11.7	8,404.14

Source: "South-Central Alaska Natural Gas Study", June 2004, Prepared for the US Dept. of Energy, National Energy Technology Laboratory, Arctic Energy Office, Contract: DE-AM26-99FT40575

Chevron currently has a \$200 million program to find new oil and gas in Cook Inlet. ConocoPhillips and Pioneer Natural resources are also active in Cook Inlet and optimistic about the prospects. Escopeta Oil contracted for a drilling rig to be approved for use in Cook Inlet in 2007 for both oil and gas exploration. The economic value with the renewed interest in Cook Inlet oil and gas will be substantial, especially to the Kenai Peninsula Borough.

It is uncertain how a beluga recovery plan may impact the economics for exploration and development of oil and gas in Cook Inlet. However, it has only been the recent spike in natural gas price that made the Inlet once again attractive for exploration. Additional costs associated with beluga recovery plan requirements and Section 7 consultation could curtail enthusiasm due to significant regulatory delays and increased costs.

COAL

The Cook Inlet – Susitna Coal Province hosts significant coal resources and include the Beluga, Kenai, Matanuska, Susitna, and Yentna coal fields. There are numerous coal leases on the Beluga and Matanuska coal fields, but no active mining is occurring at this time. The Alaska Department of Natural Resources has issued several coal exploration and mine permits within these coal fields and is in the process of coordinating the permitting of one proposed coal mine.

Beluga Field

The Beluga field is one of Alaska's most accessible sources of steam coal. Potentially mineable coal occurs in the Capps (B1), Chuitna (B2), and Threemile (B3) districts within 6 to 25 miles of port sites on Cook Inlet. Several coal seams have been identified in the area east of the Chuitna River (Diamond Coal Co., 1986); and in the area west of the Chuitna River (Placer Dome, 1986).

The Chuitna Coal Project is a surface coal mining and export development located in the Beluga coal field of Southcentral Alaska, approximately 45 miles west of Anchorage, near Tyonek. The project is based on the development of a 300 million ton, ultra low sulfur, sub bituminous coal resource, the center of the mine pit will be approximately 12 miles from the coast of Cook Inlet. The project area is largely undeveloped except for a system of primitive roadways that remain as a result of previous oil and gas exploration and production and logging activities. The workforce to support operations is anticipated at 350 people from Anchorage and the Kenai Peninsula.

The proposed Project includes: a surface coal mine and associated support facilities (Chuitna Coal Mine); mine access road; coal transport conveyor; personnel housing; air strip facility (Chuitna Project Infrastructure); a logistic center; and coal export terminal (Ladd Landing Development). The coal export terminal is currently proposed to include a 10,000-foot trestle constructed into Cook Inlet for the purpose of loading ocean-going coal transport ships. The mine will be positioned in close proximity of the Chuitna River and Lone Creek. The Chuitna River is anticipated to be proposed for use for some of the mine's wastewater and will be regulated closely by several State entities to assure its quality is protected, particularly for anadromous fish habitat. PacRim Coal, the project applicant predicts a minimum 25-year mine life based on the proven reserves in one of three mining areas within the 20,571 acre coal lease area.

If beluga whales are listed under ESA and the proposed loading area is listed as critical habitat, this would likely delay and in other ways impact construction plans of the trestle due to the required Section 7 consultation. Such delays or additional stipulations, beyond the tightly regulated mechanisms already in place under state and federal authorities, will affect the project's construction and operational economics. At the present time, studies are being conducted in anticipation of steps to reduce hydrology and noise impacts from the trestle during construction and operation in order avoid impacts to beluga and other biological and physical features of the habitat. The total economic benefit to south central Alaska from this proposed project throughout its expected life is projected to be in the hundreds of millions of dollars.

Kenai Field

The Kenai Field contains three districts – the Kenai onshore, Kenai offshore, and Seldovia – Port Graham districts (K1, K2, & K3). Coals of the Beluga and Tyonek Formations underlie extensive areas of Cook Inlet, and it is estimated that 532 million short tons of coal occur in beds more than 20 feet thick to a depth of 10,000 feet.

Matanuska Field

This field is located in the Matanuska Valley of South Central Alaska near the head of Knik Arm, 50 miles NE of Anchorage. This field contains the Wishbone Hill district, the Chickaloon district, and the Anthracite Ridge District (M1, M2, & M3). The Wishbone hill district ranks second in historic coal production; 7 million short tons of bituminous coal were extracted for railroad, power plant, and domestic use prior to 1968 (Barnes & Payne, 1956). Rocky Mountain

Energy (1986) identified 17 million tons of surface mineable coal in the Western and Northeastern parts of the Wishbone hill district. The higher ranked coals of the Chickaloon and Anthracite Ridge districts have not been fully explored due to their structural complexity (Waring, 1936).

The Wishbone Hill Mine lies at the western end of the Wishbone Hill Coal district on the southwestern extent of Wishbone Hill approximately seven miles north of Palmer, Alaska. The project is based on the development of a 13 million ton, ultra low sulfur, bituminous coal resource. The project targets four main coal seam groups area proposed for mining utilizing a truck and shovel operation. The workforce to support operations is anticipated at 100 people from Anchorage and the Matanuska-Susitna Borough.

The Jonesville Coal Mine is located in the Matanuska Valley approximately two miles northwest of Sutton, Alaska, near the southeast portion of Wishbone Hill. Mining has been conducted in this area since about 1916, and portions of as many as six separate coal seams have been removed in the past by both underground and surface methods. The project consists primarily of a surface spoils re-mining operation targeting the refuse of the former Evan Jones coal washing facility. Most of the surface disturbance will be associated with the surface re-mining operation. Annual production of re-mined material is expected to range between 350,000 and 750,000 tons.

Susitna Field

The Susitna field contains two districts: the Susitna Flats district and the Little Susitna district. Extensive areas of coal that probably correlate with the Beluga or Sterling Formations of the Kenai Group underlie the Susitna Flats district. In the area north of the Castle Mountain fault, oil-well logs show seams up to 15 feet thick in 2,000 feet of Kenai Group rocks that overlie granitic basement. Just south of the Castle Mountain fault, a well log shows a total of 301 feet of coal in 37 seams in an 8,500 foot section of the Tyonek Formation. The test well did not reach basement (Conwell, Triplehorn, and Ferrell, 1982). The Susitna district has a potential resource of 14.7 million tones of coal that is borderline between high-volatile bituminous and subbituminous A (Barnes and Sokol, 1959).

Yentna Field

Coal seams exposed in the area north of the Beluga Field generally occur in the Conglomerate and Sandstone members of the Tyonek Formation (Reed & Nelson, 1980). Less well-known than the Beluga Field, the Yentna contains drill-proven reserves in the outlying Canyon Creek and Johnson Creek districts (Y1 & Y2). The identified resources, to a depth of 250 feet and with less than a 10: 1 waste/coal ratio, are greater than 500 million short tons in the combined districts.

PORT OF ANCHORAGE

The Port of Anchorage (POA) is a Commercial Strategic Seaport serving the majority of the residents, communities, and activities within the State of Alaska. Ninety percent of all consumer goods provided to eighty percent of the State's population (along the rail belt, Aleutians, Interior Alaska, Western Alaska, and the Arctic) transit through the port. The POA also handles consumer goods for all military installations in the State and supports the rapid military deployment of the US Army's Stryker Brigade Combat Team, Aviation Task Force, and

Airborne Brigade Combat Team. When the POA officially began operations in September 1961, 38,000 tons of cargo moved across its single berth in one year. In the years since, the POA has expanded to five berths and handles five million tons of cargo, generating more than \$750 million for the State's economy.

The POA delivers jet fuel directly from the Port through pipelines to two military bases. In addition, the POA currently stages 100% of the exports of refined petroleum products from the State's largest refinery and facilitates petroleum deliveries from several smaller refineries in the State. The POA also handles delivery of approximately eighty percent of all fuel for the Ted Stevens Anchorage International Airport, the busiest cargo airfield in the United States (measured by landed weight).

The POA currently is undergoing a comprehensive expansion program to replace aging infrastructure and enhance its ability to serve the State of Alaska as a major marine cargo and cruise complex. This expansion includes creating and developing land; constructing advanced road and rail infrastructures; constructing longer and deeper dock spaces with the ability to accommodate today's larger ships; renovating and relocating existing dock structures and facilities; expanding gas and oil pipelines; and upgrading utility and communication infrastructure. Pre-expansion, the POA occupied 129 acres of land—approximately 120 acres of which serve as Port administration and tenant lease area—with the remaining approximately nine acres dedicated to road and circulation areas. Post-construction, the POA will have added 135 new acres of land, significantly increasing traffic movement throughout major industrial areas and in particular along the main arterial route supporting a combination of commercial, employee, and visitor traffic. The POA is fully operational without closure 365 days a year regardless of Alaska's harsh weather conditions.

The Port of Anchorage is the economic life line that serves the majority of Alaska. Any disruption of the Port's activities, would economically impact most, if not all, of the State of Alaska.

TOURISM

Current summer visitor volume estimates for the Kenai Peninsula total 439,000.¹ On average, visitors spend \$934 per person while in Alaska, not including the cost of transportation to enter and exit the State. For the Kenai Peninsula region where visitors tend to spend an average of 5.3 nights, this amounts to a total of \$419 million and includes money spent by air, cruise, and highway travelers. The following table illustrates estimated Kenai Peninsula average spending by visitors by transportation mode:

Total Estimated Visitor Expenditures in Kenai Peninsula Area (Millions of Dollars) Summer 2006 by Mode

	All Visitors	Air	Cruise	Highway /Ferry
Total in-state spending	\$419	\$247	\$134	\$38

Source: AVSP Summer 2006

¹ Alaska Visitor Statistic Program Summer of 2006 conducted by McDowell Group for the Department of Commerce, Community and Economic Development.

Tourism impacts will be immediately felt. Any water-based activity from cruise ships to boat tours and commercial sport fishing might be limited or curtailed depending on areas designated as critical habitat and how a beluga recovery plan is written. For example, in 2005 the Kenai Peninsula's taxable primary tourism sales totaled \$84.2 million accounting for 10 percent of total taxable sales. (source: <http://www.borough.kenai.ak.us>).

Year	Homer	Kenai	Seldovia	Seward	Soldotna	Other	Kenai Pen Borough Total
2000	\$ 12,487,597	\$ 4,827,106	\$ 440,636	\$ 19,561,615	\$ 3,204,886	\$ 27,178,838	\$ 67,700,678
2001	\$ 13,134,430	\$ 5,090,686	\$ 323,902	\$ 19,560,607	\$ 3,438,109	\$ 26,947,338	\$ 68,495,072
2002	\$ 14,371,079	\$ 4,699,916	\$ 315,411	\$ 20,304,667	\$ 4,323,213	\$ 26,900,296	\$ 70,914,582
2003	\$ 14,580,419	\$ 4,520,163	\$ 309,491	\$ 20,358,596	\$ 4,030,155	\$ 27,290,295	\$ 71,089,119
2004	\$ 15,963,723	\$ 4,693,265	\$ 302,136	\$ 21,557,817	\$ 4,506,852	\$ 30,665,855	\$ 77,689,648
2005	\$ 17,155,060	\$ 5,067,795	\$ 302,759	\$ 23,867,140	\$ 4,742,653	\$ 33,136,577	\$ 84,271,984

Source: http://www.borough.kenai.ak.us/Econ/1S_P%20data/VisitorIndustry/Sales.htm

Additionally, visitor industry business licenses totaling 8,055 in 2005 and representing 25 percent of total borough-wide businesses, account for 2,060 jobs or twelve percent of borough employment.² An important tourism-based employment segment is the Kenai River registered guides. The number of registered guides increased rapidly during 1985 – 1997, from 171 to 400. The number of guides in 2005 was 407. These guides operate on waters within the Cook Inlet watershed that could be impacted by additional restrictions on their activities.

Additional information for communities throughout southcentral and the Cook Inlet watershed can be acquired from the following statewide tourism links:

Alaska Office of Tourism Development: <http://www.commerce.state.ak.us/oed/toubus/home.cfm>
 Alaska Travel Industry Association: <http://www.alaskatia.org/>

SHORE FISHERIES AND AQUATIC FARMING

Shore fisheries authorized by the Alaska Department of Natural Resources (DNR) currently include approximately 345 leases, or lease applications, in Cook Inlet (including Kachemak Bay). During a fishery opening period, as determined by the Alaska Department of Fish and Game, set gillnets are suspended in the tide, harvested, and as the water ebbs the nets are removed from the tidelands to be cleaned and repaired. Some of the leases are for off-shore sites and must be tended by boat. Set net fishing activity occurs during the summer months of June through August. After fishing is completed, no gear or buoys remain on the tidelands. DNR collects approximately \$103,500 per year in fees from these leases. We do not have specific information on the true economic impact of the fishery because the leases are only issued to one individual per site. Often the extended family or multiple families participate in fishing one lease site, so the economic benefit is spread substantially. This estimated ex-vessel value and other economic benefits of the commercial Cook Inlet set net fishery are discussed in greater depth in the commercial fishing section of this chapter.

Aquatic farming currently authorized by the Alaska Department of Natural Resources includes approximately 18 leases in Cook Inlet; all are in Kachemak Bay. DNR collects approximately \$13,600 from the leases in Cook Inlet. One report estimates the total economic value of those

² http://www.borough.kenai.ak.us/Econ/1S_P%20data/VisitorIndustry/Earnings.htm

leases at approximately \$414,000. The distribution of these leases within the larger Kachemak Bay is: 3 in Kachemak Bay itself, 4 in Jakalof Bay, 2 in Kasitsna Bay, 3 in Peterson Bay, and 6 in Halibut Cove. They range in size from .23 to 28.6 acres, with the median being 1.95 acres. The sites are primarily for suspended oyster growth on gear comprised of vertical leads attached to buoys and mesh baskets in which the oysters grow. These are suspended in the water column and should not lay on the bottom of the ocean floor.

TRANSMISSION LINES AND PIPELINES

Approximately 22 transmission lines and oil and gas pipelines are permitted by DNR on tide and submerged lands in Cook Inlet. Most all of these rights of way were issued just after statehood in the 1960s and 1970s. These lines are either buried or laid on the submerged lands and since covered by mud. DNR expects to receive more applications for relocation or maintenance of existing facilities, construction of new facilities for new oil and gas discoveries, alternative energy projects (such as Fire Island wind generators), and tidal power generators in Cook Inlet. No new oil or gas discoveries have been announced, but there is renewed exploration activity in Cook Inlet. At present there is only one test tidal power project near Point MacKenzie on Matanuska-Susitna Borough tidelands. If that project is successful, there is a chance to see more tidal generators placed in Cook Inlet. The placement of the array of generators depends on many factors including tidal energy, substrate conditions, ice flows, navigation obstructions, and fishery considerations. The only impact from the proposed Fire Island wind farm would be the submerged power cable to the mainland.

OTHER FACILITIES

The Agrium Facility

The Agrium facility on the Kenai Peninsula could see significant expansion in the near future, which will likely involve expanded tidelands facilities, including a coal unloading facility. Agrium has a long history in Alaska, with its roots in Cominco Fertilizers Ltd which dates back to 1931.

The Kenai plant is located on the east side of Cook Inlet on the Kenai Peninsula and boasts a tidewater terminal. Products are shipped from this facility by ocean-going vessels to many parts of the world including South Korea, Mexico, and Taiwan. Kenai produces anhydrous ammonia and urea. Annual urea capacity is 640,000 tons and net ammonia capacity is approximately 280,000 tons. Kenai Storage Facility can store 73,000 tons of ammonia and 118,000 tons of dry product. Shipping is primarily by water; however, some product is shipped by truck to local agricultural and industrial markets. Agrium employs about 150 people; the employees remain on the payroll over the winter.

Port MacKenzie

Port MacKenzie is strategically placed as an area for commercial and industrial expansion adjacent to Anchorage. The Port is the only south central port site not constrained by urbanization. The 14 square miles of uplands are dedicated solely for commercial/industrial development. A ferry, bridge, and railroad spur are all programmed for Port MacKenzie. The ferry is scheduled to start operating between Anchorage and Port MacKenzie in summer 2007. Current business includes 'NPI, LLC,' an exporter of wood chips that invested \$3 million in the

Deep-Draft Dock and \$20 million in a new road, commodities storage pad, conveyor system, and equipment. The Deep-Draft Dock's total project costs were approximately \$15.4 million; aside from the creation of new jobs in the Matanuska-Susitna Borough, the project is estimated to produce \$220,000 to 600,000 in annual wharfage and dockage fees.

The ferry terminal building at Port Mackenzie was completed in October 2006, ahead of schedule. The terminal is a 7,000 square feet, two-story facility. Funding for the construction of the terminal was acquired from a Federal Transit Administration grant, and the total cost of the project was approximately \$4.5 million.

Port MacKenzie consists of a 500' bulkhead barge dock at -20' mean lower low water (MLLW), a 1,200' long deep-draft dock at -60' MLLW, and 8,940 acres (14 square miles) of adjacent uplands which are available for commercial lease. There is also a filter rock ramp adjacent to the south wingwall which is useable two hours before high tide until two hours after high tide for vessels with ramps. This allows for heavy equipment to be driven on/off the dock. The dock has a gravel surface with a load capacity of 1,000 lbs. /sq ft. The deep-draft dock is equipped with a 5' wide conveyor system capable of loading bulk commodities at 2,000 tons/hour.

Cook Inlet Ferry System

This is currently in the planning/build out stage. The ferry is now under construction. Two docks are being planned for upper Cook Inlet. Permits are in place for the Knik side, the Municipality of Anchorage has yet to issue permits for the Anchorage landing. Total investment for the project is \$44.8 million. The two planned docks could be affected if Cook Inlet beluga whales are listed under ESA.

Knik Arm Bridge Crossing

The Knik Arm Bridge and Toll Authority (KABTA), was established by the Alaska Legislature in 2003 to construct a bridge across the Knik Arm of Cook Inlet to link Anchorage to the Matanuska-Susitna Borough. To date, efforts to build the bridge have cost \$33 million, and another \$10 million is budgeted for 2007. KABATA hopes to have the bridge operational by 2010. The Federal Highway Administration has not released an environmental impact statement for the project, which KABATA completed on February 6. The fate of the proposed bridge could be affected if Cook Inlet beluga whales are listed under ESA.

MUNICIPAL WASTEWATER DISCHARGES

Since the early 1980s, Anchorage Water and Wastewater Utility (AWWU) of the Municipality of Anchorage has operated under a waiver of Section 301(h) of the Clean Water Act, allowing AWWU to discharge wastewater without secondary treatment. This waiver was given in recognition of the high mixing capacity of the tidal flats in the discharge zone, the limited number (<20) of permitted industrial discharges in AWWU's service area, and regular toxicity tests demonstrating a lack of harm to marine wildlife.

Kenai and Homer have both primary and secondary treatment facilities in place, so it is fair to state that those communities would **not** face the same level of prospective financial burden as Anchorage if an upgrade were required. Currently, AWWU of the Municipality of Anchorage is in good standing with the EPA. In spite of the track record, an ESA listing of beluga whale

would increase operational costs to rate payers due to the imposition of stricter wastewater discharge standards. A potential worst case scenario would result if the facilities permit were not reauthorized. Facility upgrades to comply with new standards could cost AWWU utility rate payers \$400 - \$600 million.

The following additional information is excerpted from correspondence by Craig Woolard, Ph.D., P.E., Treatment Division Director, Anchorage Water and Wastewater Utility:

. . .the Asplund facility which has operated since October, 1985 under a Clean Water Act 301(h) waiver which permits discharge of primary treated effluent to Cook Inlet.

In order to operate under a 301(h) waiver, AWWU conducts extensive monitoring of our treatment facility and Cook Inlet to verify that our activities are not impacting the environment. These monitoring requirements are over and above those normally placed on conventional secondary treatment plants to insure the receiving body of water is not degraded. Our monitoring activities are too numerous to mention in total here but include:

- Influent, effluent and sludge monitoring for conventional compounds (biochemical oxygen demand, total suspended solids, fecal coliform bacteria) and toxic pollutants and pesticides (126 priority pollutants that include metals and cyanide) and organics.*
- Receiving water quality monitoring to determine effluent plume dispersion and compliance with water quality standards.*
- Biological and sediment monitoring to measure toxicity of the effluent to standard test species, sediment quality, the concentration of bacteria in the Inlet, and the bioaccumulation of effluent constituents in local species (e.g., algae, salmon and cod).*

AWWU also administers an Industrial Pretreatment Program to enforce the MOA sewer ordinance and prevent local industries from discharging wastes that could impact treatment performance or Cook Inlet water quality. AWWU also supports a non-industrial source control program that partially funds the MOA hazardous waste collection facilities to prevent the introduction of harmful wastes into the sewer system.

The monitoring data show that over the last 20 years, the performance of the Asplund facility has been excellent. This facility has been operated to meet effluent limits and requirements specified in the NPDES permit and 301(h) Waiver. In fact, the Asplund treatment process achieves removal rates that are much higher than typical primary treatment facilities. The discharge itself contains very low concentrations of metals or organic materials and meets discharge requirements and water quality standards. In addition, Knik Arm provides rapid mixing and dispersion of wastewater discharged by the Asplund facility into the marine waters off Point Woronzof. As a result, our monitoring in Knik Arm has found no evidence of any significant impact of the discharge on the water quality of Cook Inlet or Cook Inlet beluga whales.

NMFS concurred with this assessment as part of our 2000 permit renewal. As part of the permitting process, EPA prepared a biological evaluation of site-specific water quality

criteria for the Point Woronzof Area and concluded that that conventional pollutant and metals discharges allowed by the NPDES permit were not likely to adversely affect beluga whales. NMFS concurred with this determination in 2000.

In addition, EPA also conducted an Essential Fish Habitat Assessment as part of the permit renewal process and concluded that issuance of our discharge permit was not likely to adversely impact any essential fish habitat in the vicinity of the discharge. Again, NMFS concurred with these findings in 2000.

MINING

The Cook Inlet watershed includes all or portions of 11 mining districts with past production greater than 2 million troy ounces of gold; more than 143 million tons of sand and gravel and more than 9.5 million tons of rock in the past 25 years; 40,000 tons of metallurgical-grade chromium ore; and significant silver, copper, antimony, and coal. Total past production value of these commodities at current commodity prices exceeds \$2.5 billion.

The area of the Cook Inlet watershed is richly endowed with mineral resources. There are over 1,500 known mineral occurrences in the Cook Inlet watershed tabulated in the Alaska Resource Data Files (ARDF) (<http://ardf.wr.usgs.gov/>). These mineral occurrences are about evenly split between placer gold and metallic lode sites. Significant gold, silver, copper, zinc, lead, nickel, platinum, chromium, tin, and antimony occurrences are known in the area, and these commodities are being aggressively explored by international mining companies in this region. In the past 5 years, mining companies have spent more than \$27.5 million exploring for minerals in the south central region of Alaska. More than 10,186 mining claims and mining leases cover State and federal lands within the Cook Inlet watershed. Significant recent mineral discoveries, such as the Whistler copper-molybdenum-gold-silver prospect near Rainy Pass, the Lucky Shot gold prospect in the Willow Creek mining district, and the Golden Zone gold-silver-copper property near the Chulitna River, may be developed in the near future. The area's excellent infrastructure and proximity to a large workforce have and will continue to attract mineral exploration for the foreseeable future.

Currently, there are no large mines operating around Cook Inlet. However, there are a large number of mineral occurrences around the Inlet, particularly along the eastern flank of the Alaska Range. The Pebble prospect is the obvious prospect for a large mine in the foreseeable future. A number of companies are exploring in the area north and west of Iliamna near the Pebble prospect. On the other side of Cook Inlet, there is a chromite deposit at Red Mountain, on the southern end of the Kenai Peninsula. There is presently no activity on the deposit, but it has been mined in the past and could be developed in the future. The deposit is on Cook Inlet Region Inc. (CIRI) land. Full Metal Minerals is doing development drilling on the old Lucky Shot gold mine on upper Willow Creek in the Talkeetna Mountains, with a good possibility of developing that prospect into a working mine again. The Lucky Shot will likely be a small operation, and farther away from Cook Inlet. This deposit is small but has good values and could become a mine in the future. The Johnson River prospect is on CIRI land.

Currently no shoreline or offshore mining activities occur around Cook Inlet. Hemis Gold is beginning an offshore sampling program in the Anchor Point area this year.

The Pebble Project

The Alaska Department of Commerce, Community and Regional Development recently did an evaluation of the economics of a base case mining operation at the Pebble prospect. The base case considered that the mine would be developed as a combination underground and open pit operation with milling at site. Mineral concentrates would be shipped by pipeline to Cook Inlet to a port located near Williamsport.

It is anticipated that typical operation of Pebble, although not yet proposed by the operator, would involve mining 80,300,000 tons of ore annually. Development costs would be in the order of \$4 billion for this typical scenario and employ several thousand persons, many from the immediate area. Direct operating employment would be in the order of 3,500 persons on a full time basis. Other elements of the base (typical) case would be:

- Power would be provided from the Kenai Peninsula
- Concentrates would be shipped worldwide for smelting and metals recovery
- Tailings from the milling operation at site would be placed in a tailings pond (lake) to prevent oxidizing and mobilizing sulfides and metals
- Cost of labor was assumed to be 40% of the total operating cost for the operations; wages would average \$85,000 annually plus 35% burden and benefits
- The base case operating cost was calculated to be \$12.50 per ton milled.

Operation of the property would have a significantly positive economic impact to southwest Alaska and the State. The results of preliminary tax calculations indicated that the mine would pay average annual revenues as follows:

- Municipal taxes of \$23.3 M
- Total state revenues of \$141.1 M (mining license and income taxes, production royalty and claim lease payments).

The project would contribute to indirect employment of a certain percentage, probably equal to or exceeding the direct employment at the operation. This would add at least another 3,500 jobs to the immediate area and the State. Fairbanks Gold's Ft. Knox property is estimated to contribute \$180 million per year to the economy of Fairbanks and vicinity; the Pebble project would be several orders of magnitude larger than Ft. Knox suggesting a tremendous economic influence. This economic boost could easily be in the order of \$500 million annually.

TIMBER

Approximately 39,203 acres of state, private, and borough land could be harvested for timber over the next 20 years within the Cook Inlet watershed. A summary of these harvests is shown below.

PROJECTED TIMBER HARVEST ACTIVITY IN COOK INLET WATERSHED					39,203 acres				
Division of Forestry estimates of likely timber harvest activity in the Cook Inlet watershed, 2007-2027. Actual harvests will depend on market demand and forest management decisions by the landowners.									
Total within 5 years (2007-2011)					Total within 5-20 years (2012-2027)				
		State	Other	Total	Notes	State	Other	Total	Notes
High Probability	Mat-Su	1,000	1,500	2,500	Small sales to local mills on state, Native, and Borough land; plus land use conversions on other private land; limited harvesting for chips	3,000	1,000	4,000	Small sales to local mills
	Kenai Peninsula	2,500		2,500	Ongoing sales of spruce beetle-killed timber	1,500		1,500	
	W. Side Cook Inlet	0	0	0					
Moderate Probability	Mat-Su	2,800	500	3,300	Additional harvesting for chips or pellets -- 2800 acres State sales, 1000 ac Borough sales, approx. 1500 ac in Native sales+ private land use conversions	7,000-12,000	200-400	700-1200	Additional harvesting for chips or pellets
	Kenai Peninsula	7,000	2,000-5,000	9,000-14,000	Additional harvesting for pellets				
Low Probability	Tyonek		5,000	5,000	Harvesting for chips on Native and Mental Health land in Tyonek area				Harvests could occur on Tyonek land if harvest is not complete in first 5 years
	Tuxedni Bay		2,400	2,400	Native land at Crescent River				see notes
	Kalgin Island	1,100		1,100					
	S. Kenai Pen.						500-1,000		Native land Seldovia to Port Chatham
	Jakolof Bay						500		Mental Health Land/Native land
	W. Side Cook Inlet						2,000		Native land

FISHERIES

The statutory responsibility of the Alaska Department of Fish and Game is to protect, maintain, and improve the fish, shellfish, and aquatic plant resources of the State, consistent with the sustained yield principle for the maximum benefit of the economy and the people of Alaska. The following comments address examples of the economic impact of designating critical habitat aspect of a proposed listing under ESA.

The Alaska Department of Fish and Game manages all fish stocks for sustained yield under the mandate of the Alaska Constitution and manages salmon according to the regulatory policy for the management of sustainable salmon fisheries, 5 AAC 39.222, which is based in part on the goal of ensuring “*conservation of the salmon and the salmon’s required marine and aquatic habitats.*”

- **SUBSISTENCE FISHERIES**

Most of the waters of the Cook Inlet Management Area are within the Anchorage-MatSu-Kenai Nonsubsistence Area as established by the Joint Boards of Fisheries and Game (5 AAC 99.015(3)). Subsistence fisheries are not authorized within these nonsubsistence areas. Non-commercial harvesting opportunities are provided under sport and personal use fishing regulations.

Cook Inlet waters outside the nonsubsistence area include the Tyonek Subdistrict and the western portion of the Susitna River drainage in Upper Cook Inlet, plus those waters north of Point Bede which are west of a line from the eastern most point of Jakolof Bay north of the westernmost point of Hesketh Island including Jakolof Bay and south of a line west of Hesketh Island and the waters south of Point Bede which are west of the easternmost point of Rocky Bay, which are in Lower Cook Inlet. These are areas where the Joint Board found subsistence fishing and hunting to be a principal characteristic of the economy, culture, and way of life, the standard established by Alaska statute (AS 16.05.258(c)) to identify areas where subsistence hunting and fishing will be permitted.

Cook Inlet communities outside the nonsubsistence area include Skwentna (population 111 in 2000), Alexander (population 39), Tyonek (population 193), Seldovia (population 430), Port Graham (population 171), and Nanwalek (population 177). These communities have economic attributes directly linked to decisions regarding management of the subsistence fisheries and related access to those fisheries.

Outside the nonsubsistence area, the Alaska Board of Fisheries is required to identify fish stocks with customary and traditional uses and adopt regulations that provide a reasonable opportunity for subsistence uses of those stocks. If the harvestable surplus for any fish stock with customary and traditional uses is not sufficient to provide opportunities for all consumptive uses, non-subsistence uses must be restricted or eliminated before restricting subsistence fishing opportunities (AS 16.05.258). All Alaska residents are eligible to participate in authorized subsistence fisheries.

The Alaska Board of Fisheries has adopted regulations for 4 subsistence salmon fisheries in the Cook Inlet Area. Brief descriptions follow. For more detail, see Fall et al. 2007.

1. Port Graham and Koyuktoik Subdistricts. This subsistence setnet salmon fishery is located along the southern shore of outer Kachemak Bay in the Port Graham and Koyuktoik subdistricts of the Southern District and, beginning in 2002, the Port Chatham and Wind Bay subdistricts. Two Alaska Native communities, Nanwalek and Port Graham, are located in the Port Graham Subdistrict, and residents of these communities are the primary participants in the fishery. The recent (2001 to 2005) annual harvest for this fishery was 8,000 salmon (Table S1). For a detailed description of this subsistence fishery and other subsistence harvests and uses in Nanwalek and Port Graham, see Stanek (1985).

2. Seldovia Subsistence Salmon Fishery. This setnet fishery is located on the south side of Kachemak Bay in the vicinity of the community of Seldovia in the Southern District of the Lower Cook Inlet Area. It targets Chinook salmon runs passing through lower Cook Inlet and a separate enhanced Chinook run returning to Seldovia Bay. Coho salmon are targeted in a fall fishery. Most participants in the fishery live in Seldovia. The recent (2001 – 2005) annual harvest in this fishery was 342 salmon (Table S2).

3. Tyonek Subdistrict Subsistence Salmon Fishery. This subsistence setnet fishery is located in the Tyonek Subdistrict of the Northern District of upper Cook Inlet. The subdistrict includes the area from one mile south of the mouth of the Chuitna River south to the eastern-most part of

Granite Point and from the mean high tide to the mean lower low tide. Most fishery participants live in Tyonek. From 2001 through 2005, the average annual harvest in the fishery was 1,346 salmon, mostly Chinook salmon (Table S3). For a detailed discussion of this fishery and other subsistence uses at Tyonek, see Fall et al. (1984).

4. Upper Yentna River Subsistence Fish Wheel Fishery. This is a subsistence fish wheel fishery that began in 1996 as a personal use fishery and was reclassified as a subsistence fishery by the Board of Fisheries beginning in 1998. It is located in the main stem of the Yentna River from its confluence with Martin Creek upstream to its confluence with the Skwentna River. Legal gear includes a fish wheel with a live box. Over half the participants are residents of the Skwentna area. From 2001 through 2005, the average annual harvest was 553 salmon (Table S4).

• RECREATIONAL AND PERSONAL USE FISHERIES

The following three marine sport and personal use fisheries are examples of the broad attributes of sustainable managed fishing effort and harvest in Cook Inlet. Additional information regarding guides and businesses involved in these fisheries may be available from the required guide/charter registration and logbook program. The fisheries and descriptions are:

1. Turnagain Arm hooligan personal use dipnet fishery open only to Alaska residents, occurs in upper Turnagain Arm and Twentymile River from mid-May to late June. Fishing effort and harvest information is available in the Statewide Harvest Survey reports and recent Anchorage Area Management Report.
2. Central Cook Inlet marine recreational fishery primarily targets halibut and Chinook salmon, some coho salmon; occurs from mid-May through August, with most effort mid-May through July. Most boats launch from Deep Creek and Anchor River on the Kenai Peninsula, with some effort occurring by fishermen launching at Homer. Guides/charters and area businesses (Kasilof south to Anchor Point and to some degree Homer) are dependent on these fisheries. Effort and harvest information is in the Statewide Harvest Survey reports and recent North Kenai Peninsula Area Management Report.
3. Lower Cook Inlet marine recreational fishery primarily targets halibut and Chinook salmon, some rockfish; occurs nearly year-round with most effort May-August targeting mostly halibut, though some Chinook effort, and lower levels of effort September-April targeting feeder

Chinook. Most fishermen launch from Homer and Seldovia. Guide/charters and area businesses in Homer/Kachemak Bay are dependent on these fisheries. Effort and harvest information is in the Statewide Harvest Survey reports, recent Lower Cook Inlet Area Management Report, and Groundfish Area Management Report.

The salmon personal use fishery primarily occurs at the mouth of the Kenai and Kasilof rivers, with set net personal use fishery in marine waters near the mouth of the Kasilof. The fishery takes place from mid-June to mid-August, with most effort from late-June to end of July. Guiding is minor, but businesses in the Kenai, Soldotna, and Kasilof area are intensively involved. Effort and harvest information is in recent Upper Kenai Peninsula Area Management Reports and an report by Reimer and Sigurdsson.

The last study the Alaska Department of Fish and Game contracted to provide an estimate of the economic impact of sport fishing activities within the Cook Inlet region was published in 1999 for the 1993 fishing year. The estimates contained within the report are based on data that is now over a decade old, so the economic estimates contained in the report are likely underestimates of the current economic impact of fishing activities. The report is available at <http://www.iser.uaa.alaska.edu/ResourceStudies/sportfishing.htm>. Updated estimates of the economic impact of sport fishing specific to the Cook Inlet region will be available in December 2008, as part of a new study contracted by the Department in February 2007.

In March 2006, the University of Alaska Institute of Social and Economic Research (ISER) published a report under contract with the Kenai River Sport Fishing Association, which focused on estimating the economic benefits of sport fishing, personal use, and commercial fishing in Upper Cook Inlet. The economic estimates in the report were developed by aggregating available information from a variety of sources (including the Department's 1993 economic study) to produce updated estimates based upon several economic assumptions (KRSA 2006). The National Marine Fisheries Services (NMFS) has also conducted several recent economic studies within south central Alaska and Cook Inlet, focusing on recreational saltwater fisheries. The economic estimates associated with sport fishing in Alaska produced by these and other studies, along with the methodology used, scope of work, are summarized in a historical spreadsheet prepared by Department staff below. A summary of the available economic impact of just salmon sport fishing in the south central region and for Upper Cook Inlet waters in 1993 and 2003 is noted in the following table below (KRSA 2006)

Economic Contribution	1993¹	2003²
A. Total Expenditures³ (millions \$)		
Southcentral Alaska	338	415
Upper Cook Inlet salmon	N/A	246
B. Total Payroll⁴ (millions \$)

³ Direct expenditures by anglers for costs related to sport and personal use fishing

⁴ Total wages and salaries generated by direct and indirect spending arising out of sport fishing activity.

⁵ Total average annual (full time equivalent) jobs created by direct and indirect effects of sport fishing expenditures.

⁶ collective economic gain attributable to residents and nonresidents measured as the monetary value that participants place on the benefits they receive from fishing over and above the cost of going fishing

⁷ total direct spending (expenditures plus net economic value for residents and non-residents)

The Department maintains a current database of the number of license sport fishing guides and guide businesses in the Guide Licensing Database. In 2006, the following counts of sport fishing guide business for Cook Inlet (by water type) were available:

685 = the total number of licensed guide businesses in communities around Cook Inlet in 2006

295 = the total number of licensed guide businesses that operated in saltwater in 2006^a

358 = the total number of licensed guide that operated in freshwater in 2006^b

^a some guided businesses based in one community may actually operate in non-Cook Inlet saltwaters (i.e., North Gulf Coast or Prince William Sound)

^b I did not analyze what fishery/what freshwaters these businesses fished in and thus the count may include business that operate in non-Cook Inlet based freshwater fisheries.

Detailed lists of the guide businesses by community and water type are available from the ADF&G Guide Licensing Database as well.

The following references provide additional information on Economics of Sport Fishing in Alaska. Although several address sport fishing economics in parts of Alaska outside of Cook

Inlet, the methodology and information sources should be helpful to any analysis conducted on economic attributes of sport fishing.

- **COMMERCIAL FISHING**

According to the Alaska Department of Commerce, Community and Economic Development, the economic impacts and economic attributes involving the Alaska Department of Fish and Game's closely regulated and sustainable management of commercial salmon fishing in Cook Inlet would be significant. For example, the combined salmon harvests of Upper and Lower Cook Inlet range between three and six million total salmon in any given year. In the Upper Cook Inlet, this includes the valuable sockeye salmon, which in 2006 were worth \$12.3 million or about 90% of the total ex-vessel value to fishermen. In 2006, Upper Cook Inlet total salmon ex-vessel harvest was worth \$13.72 million. Lower Cook Inlet total ex-vessel harvest last year was worth \$1.9 million. Total Cook Inlet salmon (ex-vessel) value was \$15.6 million, just slightly above the recent 5-year average:

5-Year Average Harvest Value: \$14.7 million
5-Year Average Permits Fished: 982
5-year Average Harvest (# of salmon): 5.3 million

The ex-vessel value does not include the significant multiplicative effect of the economic activity generated by commercial fishing operations in the region. This role supports retail for groceries and supplies in the communities, employment and business in seafood processing, the portion of the salmon prices that is automatically contributed to communities for schools and other infrastructure, transportation for fishermen and fish, service providers, fuel, housing, etc.

Details of the economics and attributes of the commercial fisheries follow:

Historically, commercial fishing activity has occurred in Cook Inlet well before Statehood in 1959. The first documented report of commercial fishing began in the 1880s and continues today. The commercial fishing industry located in Cook Inlet contributes significantly to the overall economy of the South Central region of the state.

Salmon fishing comprises the majority of the harvest and value of present day commercial fishing activity in Cook Inlet. During the most recent ten years (1997–2006) over 286 million pounds of salmon have been processed in Cook Inlet for a combined exvessel value of nearly \$189 million dollars. During 2006 alone, 481 salmon set gillnet permits, 396 salmon drift gillnet permits and 24 salmon purse seine permits fished.

The Pacific cod and herring fisheries represent two additional commercial fisheries in Cook Inlet. Pacific cod fisheries in Alaska are managed by both the federal and state governments. State-managed fisheries for Pacific cod began in 1997 and are distinct from the parallel fisheries. Parallel fisheries for Pacific cod occur in state waters at the same time as the federal fisheries in Cook Inlet and harvest against the federal total allowable biological catch. State-managed Pacific cod fisheries allow only pot and jig gear types to harvest against a fixed portion of the total allowable biological catch that is allocated to the State fisheries.

The Pacific cod fishing fleet has decreased from 167 vessels with a harvest of 4.1 million fish in 1997 to 56 vessels with a harvest of 2 million fish in 2006.

Limited commercial herring fishing activity occurs in Cook Inlet. There has not been a directed herring purse seine opening since 1998. On average, about one dozen permits participate annually in the herring roe gillnet fishery.

The Cook Inlet area is subdivided into the Upper Cook Inlet (UCI) and Lower Cook Inlet (LCI) management areas.

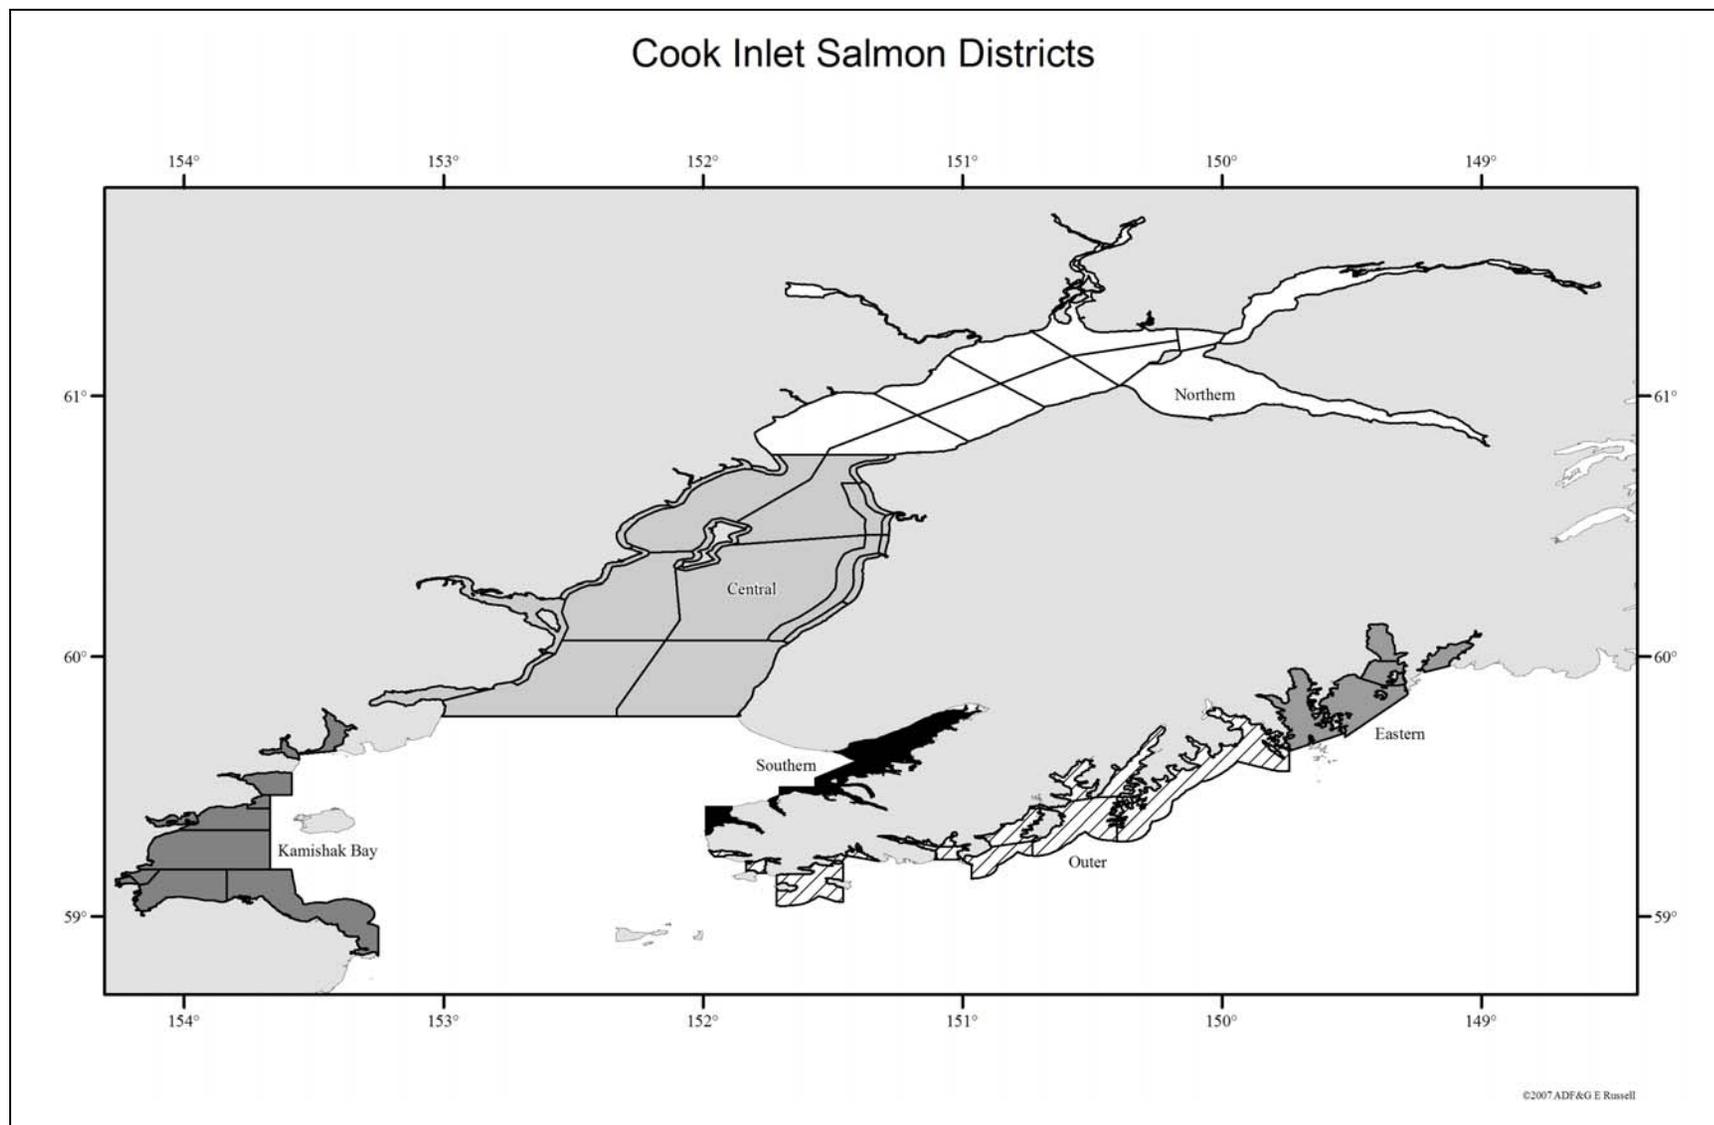

Figure 1.—Map of Upper and Lower Cook Island salmon districts.

UPPER COOK INLET

The UCI management area consists of that portion of Cook Inlet north of the latitude of Anchor Point and is divided into the Central and Northern Districts (Figure 2). The Central District is approximately 75 miles long, averages 32 miles in width, and is further subdivided into six subdistricts. The Northern District is 50 miles long, averages 20 miles in width and is divided into two subdistricts. At present, 5 species of Pacific salmon (*Oncorhynchus*) and Pacific herring (*Clupea harengus pallasii*) represents the majority of commercial harvest in UCI.

SALMON

Since the inception of a commercial fishery in 1882, many gear types, including fish traps, gillnets, and seines, have been employed with varying degrees of success to harvest salmon in UCI. Currently, set (fixed) gillnets are the only gear permitted in the Northern District, while both set and drift gillnets are used in the Central District. The use of seine gear is restricted to the Chinitna Bay Subdistrict, where they are employed sporadically. Drift gillnets have accounted for approximately 50% of the average annual salmon harvest since 1966, with set gillnets harvesting virtually all of the remainder.

HERRING

Commercial herring fishing began in UCI in 1973 with a modest harvest of bait-quality fish along the east side of the Central District and expanded in the late 1970s to include small-scale sac roe fisheries in Chinitna and Tuxedni bays. In 1988, significant decreases in herring abundance were observed in Tuxedni Bay, as well as a shift towards older age class herring, resulting in the closure of Tuxedni Bay to commercial herring fishing prior to the 1992 season. In Chinitna Bay and along the eastside beaches, similar declines began to materialize after the 1990 season.

In 1998 the Upper Subdistrict of the Central District and the Eastern Subdistrict of the Northern District were opened to commercial herring fishing to assess the status of the herring population. The herring fisheries on the west side of Cook Inlet remained closed until the status of the east side stocks was determined.

The Central District Herring Recovery Management Plan, which became active prior to the 1999 season, limited herring fishing in UCI to the waters of the Upper, Western, and Chinitna Bay Subdistricts. In the Upper Subdistrict, fishing for herring is not allowed within 600 feet of the mean high tide mark on the Kenai Peninsula to reduce the interception of salmon. The management plan was amended by the Board of Fisheries (BOF) prior to the 2002 fishing season, extending the closing date for the fishery an additional 11 days to May 31.

In 2001, samples of herring were collected in Chinitna and Tuxedni Bays. Age, sex, and size distribution of the samples revealed that the years of closed fishing in these areas had resulted in an increase of younger fish being recruited into the population. As a result of these analyses, and in accordance with the herring management plan, the commercial fishery was reopened in 2002 in both the Chinitna Bay and Western Subdistricts. The management plan allowed for a very conservative harvest quota, not to exceed 40 and 50 tons, respectively. There has been very little participation in either fishery since they were reopened. However, there has been limited food/bait harvest in the Central District in 1999, and from 2002 through 2004.

Because the glacial waters of UCI preclude the use of aerial surveys to estimate the biomass of herring stocks, management of these fisheries has departed from the standard techniques employed in the more traditional herring fisheries. Gillnets are the only legal gear for herring in UCI, with set gillnets being used almost exclusively. This gear type is significantly less efficient at capturing herring than purse seines. Moreover, conservative guideline harvest levels have been set, which provide for a low-level commercial fishery on these stocks. In the Upper Subdistrict, harvests are generally concentrated in the Clam Gulch area, with very little or no participation in either the Western Subdistrict (Tuxedni Bay), Chinitna Bay, or Kalgin Island subdistricts.

LOWER COOK INLET

The Lower Cook Inlet (LCI) management area, comprised of all waters west of the longitude of Cape Fairfield, north of the latitude of Cape Douglas, and south of the latitude of Anchor Point, is divided into five commercial salmon fishing districts (Figure 3). The Barren Islands District is the only fishing district where no salmon fishing occurs, with the remaining four districts (Southern, Outer, Eastern, and Kamishak Bay) separated into approximately 40 subdistricts and sections to facilitate management of discrete stocks of salmon.

SALMON

Chinook and coho salmon are not normally commercially important species. However, the set gillnet fleet comprises the majority of the Chinook salmon catch. While sockeye salmon harvests are experiencing lower than average harvests in recent years, pink (the dominant salmon species in numbers of fish) and chum salmon harvests are higher than average. Participation levels in the salmon set net fishery remain low, while participation levels in the purse seine fleet show a slight increase in recent years.

HERRING

Since 1973, the majority of LCI sac roe herring harvest and effort has occurred within the Kamishak Bay District. With the exception of a test fishery in 1999, there has been no directed commercial herring fishery since 1998 because the spawning biomass has been below the threshold of 6,000 set before a commercial sac roe harvest can be considered for Kamishak Bay.

PACIFIC COD

Historically, the Cook Inlet area commercial Pacific cod fishery was managed via emergency order to coincide with seasons in the adjacent federal Central Gulf of Alaska area (CGOA). The Cook Inlet Pacific Cod Management Plan (5 AAC 28.367), first effective in 1997, defines two seasons, a “parallel season” and a “state waters season.” Similar to historical seasons, the parallel season is set by emergency order to coincide with the federal CGOA fishery for Pacific cod with respect to season dates and allowable gears—provided those gear types are legal for state waters. The state waters season occurs 24 hours after the parallel season closes, but with allowable gear types restricted to pot or jig (mechanical or hand) and with an annual allocation equal to 3.75% of the federal CGOA allowable biological catch. Season dates for these fisheries are shown in Table 9.

Annual Pacific cod harvests in the Cook Inlet Area have declined sharply since 1999 due primarily to a shift of longline effort from Cook Inlet to the Kodiak management area. Since 2002, overall harvest has remained somewhat stable at between 2.0 million and 2.5 million pounds, primarily from pot gear. The number of vessels in the pot fishery has ranged from 25 in 1999 to 10 from 2001 to 2003. The 2007 harvest is expected to be comparable to recent years.

Table 8.—Cook Inlet Area commercial Pacific cod harvest by gear type and estimated exvessel values, 1997–2006.

Year	Vessels	Landings	Jig/troll	Pot	Longline	Net Gear	Harvest	Value (\$)

	March 1-May 1, June 15-October 2	State seasons pots

^a All season openings and closures occurred at 12:00 noon unless otherwise noted.

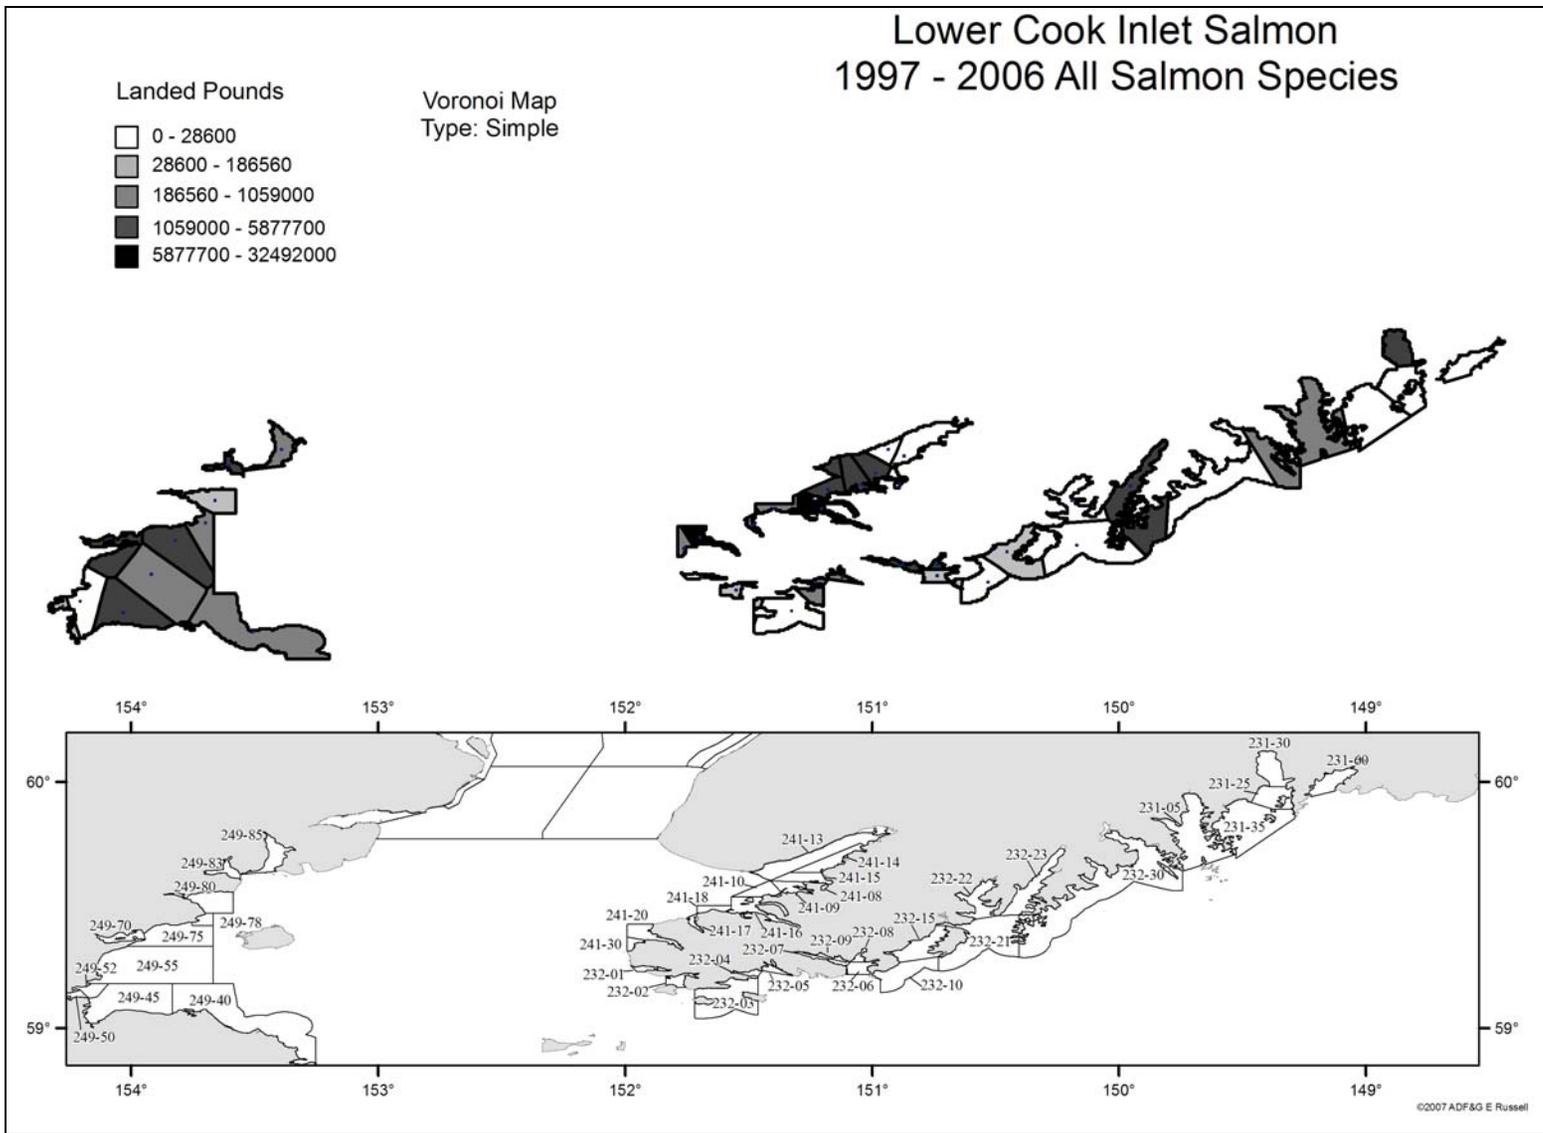

Figure 3.—Map of Lower Cook Inlet salmon.

FISHING SEASONS

Fishing seasons vary in Cook Inlet. In the salmon fisheries, the drift gillnet season is open from late June through August; the set gillnet season is from June through September and the purse seine season is from June through August.

The herring fishery is usually open from mid-April through mid-May. The Lower Cook Inlet has not had a directed commercial herring opening since 1998.

The Cook Inlet commercial Pacific cod season is comprised of three to four opening periods represented by allowable gear type and management plan. The parallel season (concurrent with federal season) is from January through March and the state waters fishery is open intermittently from February through December.

COMMERCIAL FISHERIES IMPACT

Commercial fishing processors operating in Cook Inlet reported total combined fishery purchases of \$449 million dollars between 1997 and 2006. The first wholesale value alone accounts for over \$1 billion dollars in sales between 1997 and 2005 (ADF&G COAR Database). Curtailment of commercial fishing due to adoption of a critical habitat designation may result in a depressed commercial fishing industry economy.

The Department concurs with the Service's finding: "There is no indication at this time that competition with commercial fishing operations is having any significant or measurable effect on CI beluga whales" (Draft Conservation Plan for the Cook Inlet Beluga Whale, U.S. Department of Commerce and NOAA, March 16, 2005). Based on this finding, designated important commercial and recreational fishing areas and fishing support facilities within Cook Inlet should be excluded from any designation of critical habitat. Economic benefits of exclusion outweigh any marginal benefit that might accrue from such designation.

36

CONCLUSION

As illustrated by the examples of various economic activities in Cook Inlet described above, it will be difficult to determine the economic impact that a listing of Cook Inlet beluga whales or any PCE or critical habitat may have. The industries and communities that engage in activities in and around Cook Inlet are just now assessing the possible ramifications of a beluga listing under ESA. If the whales are listed under ESA, it would certainly change the economic landscape of Southcentral Alaska and most likely have an impact through out the State.

We urge the Service to carefully consider the many activities in the Cook Inlet watershed and the many effective steps that have been effectively and proactively implemented to eliminate or reduce impacts on the beluga whales and their habitat, and thereby mitigate the decline of beluga whales in the 1990s. The Port of Anchorage currently has an operational plan in place designed to minimize the Port's impact on beluga whale's activities. Exploration companies are seeking ways to minimize disturbing operations that could be detrimental to the beluga's free range. We must continue to employ means of conducting business in and around Cook Inlet that will assure the coexistence of commerce and the beluga whale population.
