## Abstract

Shungnak is a small Iñupiaq Eskimo community on the Kobuk River in northwest Alaska. Most of Shungnak's 248 residents depend substantially upon locally harvested wild foods for their subsistence. This report provides an estimate of subsistence harvests by Shungnak residents during calendar year 2002, and is the first comprehensive estimate of subsistence harvests on record for the community.

Data were gathered with a comprehensive subsistence harvest survey administered February 1-8, 2003, to 51 of 54 Shungnak households (a 94 percent sample). The survey included questions about the harvest of fish and wildlife by each household, the members of each household, the jobs held and income earned by each member of each household, and other information. Harvests were collected as numbers, then converted to edible pounds using standard conversion factors.

Analysis showed that residents of Shungnak harvested an estimated 151,911 pounds of edible wild food in 2002. The average harvests were 2,813 pounds per household and 610 pounds per person. Shungnak's average household harvest was similar to average household harvests estimated for other northwest Alaska communities during the past two decades.

Shungnak's harvest included 49 different species or species categories. The largest harvest of a single species was caribou. An estimated 403 caribou were harvested, providing 54,864 edible pounds or 36 percent of the total community harvest by weight. Humpback whitefish provided 40,615 pounds ( 27 percent), chum salmon 22,858 pounds ( 15 percent), sheefish 11,111 pounds ( 7.3 percent), and moose 5,696 (3.8 percent). Comparison with previous harvest estimates for selected species showed harvests in 2002 were generally lower than in 1993 (for birds), and 1998 (for land mammals).

Social network data showed extensive cooperation among households. In response to a series of social network questions exploring 16 different household support activities, the 51 sampled households reported 4,350 instances of household support. Of those, 2,521 instances were for wild food harvesting, processing, or distribution. The Shungnak network data were more extensive than those collected by a previous study in Wales and Deering. Shungnak households provided an average of 85 reports of household support activities, 49 of which were for harvesting, processing, and distribution. By comparison, households in Deering reported 22 instances of harvesting, processing, and distribution per household, and Wales reported 18 instances per household.

## Acknowledgments

This report was made possible by the support of the residents of Shungnak, who graciously answered hundreds of survey questions during a gray week in February. We appreciate your patience and your good humor during surveys that lasted, on average, more than an hour and sometimes two or three hours.

Caroline Tickett, Elaine Tickett, Gary Tickett, and Robert Waters administered surveys, providing the data without which this report would be impossible. The staff of the Shungnak IRA were especially helpful. President Frederick Sun and administrator Linda Lee supported the project from the initial proposal through survey administration to the final report. Lizzie Cleveland, Judy Lee, and Cheryl Mitchell promptly responded to all our requests, verified household lists, and made sure that local researchers got paid. Sherman Minter, principal of the Shungnak school, made the high school gymnasium available for a community meeting at the beginning of the project.

This project wouldn't have begun without the vision of Ken Adkisson, subsistence coordinator for the Western Arctic National Parklands of the National Park Service. NPS' Don Callaway gave the survey instrument his usual careful scrutiny, greatly improving the quality of the questions and the depth of the inquiry. NPS cultural anthropologist Eileen Devinney came to Shungnak, helped with the training session, and went door-to-door with the rest of us administering surveys, which is the only way to really know what the data from a survey project might mean.

For the Alaska Department of Fish and Game, Renee Foster, Ana Lewis, Kathleen Sherman, and Jim Simon kept the administrative wheels turning, the often invisible but essential work that prepares cooperative agreements for signature, codes invoices for payment, and processes travel claims for reimbursement. We were motivated in part by Jim Dau, who is always eager for good information, yet appreciative of the difficulties in gathering it. And as always, the nature of our research is constantly influenced by the good judgment and clear vision of Susan Georgette, who questions our ideas, challenges our hypotheses, tweaks our surveys, and edits our reports with a rare clarity of purpose.

## InTRODUCTION

This report presents selected findings from a comprehensive community survey conducted in Shungnak, Alaska, in January, 2003, by the Alaska Department of Fish and Game, the National Park Service, and the Native Village of Shungnak. The survey was intended to document the subsistence harvests of wild foods by the residents of Shungnak, and to describe other social and economic aspects of the community. Additional findings from the survey will be available in a Community Profile Database maintained by the Alaska Department of Fish and Game.

This project was funded by the National Park Service's Western Arctic National Parklands, under
a cooperative agreement with the Alaska Department of Fish and Game's Division of Subsistence. The Division of Subsistence, in turn, signed a cooperative agreement with the Native Village of Shungnak to conduct the surveys and review project reports.

## Background

Shungnak is a small Iñupiaq Eskimo community on the Kobuk River in northwest Alaska, about 744 kilometers ( 462 miles) northwest of Anchorage (Figure 1-1). It is one of three communities on the upper Kobuk River. Ambler is located 40 kilometers (25 miles) northwest of Shungnak, downriver. Kobuk is located 12 kilometers ( 7 miles) east of Shungnak,

Figure 1-1. The upper Kobuk River, including the communities of Ambler, Shungnak, and Kobuk.

## Introduction

upriver. In the 2000 census, Shungnak reported 256 residents, Ambler 309, and Kobuk 109.

The Kobuk River flows entirely within the Northwest Arctic Borough, a political subset of the State of Alaska that encompasses 35,898 square miles, and also includes the Noatak River drainage, the Selawik River drainage, the Buckland River drainage, portions of the northern Seward Peninsula, and the coast northwest of Kotzebue. The Northwest Arctic Borough included 11 communities, with 7,208 residents. The residents of these communities are predominately Iñupiaq Eskimo, and the communities are sustained by a mixed cash-subsistence economy.

Ninety percent of the residents of the three upper Kobuk River communities were Iñupiaq Eskimo. In Shungnak, 94 percent were Iñupiaq. Almost all were descended directly from or related by marriage to members of a single society that inhabited the upper Kobuk River in the late nineteenth century, the Kuıvaum Kaךiaġmiut (Burch 1998a:126). The Kuиvaum Kaniaġmiut occupied the Kobuk watershed from Ambler River upstream to the headwaters, an area of approximately 6,500 square miles including the Mauneluk, Pah, Selby, Beaver, and Reed rivers. They were semi-nomadic, moving seasonally to fish and hunt at various locations, returning usually to the same winter settlements. In addition to the upper Kobuk watershed, Kuuvaum Kayiagmiut also ventured north into the upper Noatak watershed to hunt caribou and sheep.

Burch listed eleven Kuuvaum Kayiagmiut settlements for 1870, with a total population of 624-680 people (Burch 1998a:137). The $19^{\text {th }}$ century communities were further upriver than the $20^{\text {th }}$ century communities, and they were gradually abandoned during the early $20^{\text {th }}$ century. The inhabitants resettled in one of the three contemporary communities. Kobuk was founded in 1900 by miners who discovered gold in nearby streams, and by 1910 Kobuk's school, church, trading post, and mining employment had attracted 204 Iñupiaq residents. Shungnak was founded about 1927 by Iñupiat from Kobuk who were tired of persistent flooding that plagued the Kobuk site. Ambler was founded about 1957 by several Iñupiat families from Shungnak.

In 2000 the upper Kobuk was inhabited by 674 people. Interestingly, that was approximately the
same number of people Burch estimated for 1870.
Regardless of where they settled along the upper Kobuk River, though, the Kuuvaum Kayiagmiut considered the upper Kobuk to be their territory. Other than teachers and the occasional miner or trapper, few other people lived there, and fewer still stayed for more than a few years.

After the Alaska Native Claims Settlement Act (ANCSA) was passed by Congress in 1971, Kuuvaum Kaŋiaġmiut became minority land owners in their homeland. The federal government owned about 50 percent of the land; the state government about 40 percent. About 10 percent of the land in the area was private, owned by the NANA Regional Corporation - a native profit corporation created by the Alaska Native Claims Settlement Act to manage native lands and resources in northwest Alaska. Individuals owned less than 1 percent of the area, mostly as Native allotments.

Like other communities in the Northwest Arctic Borough, the cash sector of the local economy depended heavily upon government services like education and municipal government, and upon direct transfer payments to individuals like the Alaska permanent fund dividend. The Alaska Department of Community and Economic Development estimated that 52 percent of the adults in Shungnak were not working, and 36 percent of Shungnak's residents had incomes below federal poverty guidelines (2003).

Throughout the $20^{\text {th }}$ century and into the $21^{\text {st }}$ century, residents of Shungnak depended substantially upon the local harvest of wild foods, including caribou, salmon, sheefish, whitefish, and moose for subsistence. Subsistence hunting and fishing in the vicinity of Shungnak are managed by State of Alaska and by several federal agencies. In addition, NANA controlled access to extensive corporation lands in the area, granting free access to shareholders and their families, and granting permits to a handful of long-term non-Native residents. The National Park Service manages three conservation units in the vicinity of Shungnak: the Kobuk Valley National Park, the Noatak National Preserve, and the Gates of the Arctic National Park and Preserve. The U.S. Fish and Wildlife Service manages the Selawik National Refuge.

Management of fish and wildlife resources and control of access to local lands were critical issues

## Introduction

for Shungnak residents in 2003. Non-local, recreational use of the upper Kobuk has increased rapidly during the past 25 years. Except on NANA corporate lands and private allotments, they were unable to control access to the lands and use of the lands. This created conflicts between local residents and non-local hunters and sport fishermen (Georgette and Loon 1990; Magdanz 2000).

Under both state and federal law, subsistence uses have a priority over other consumptive uses of fish and wildlife. Providing that priority requires information about the nature and extent of subsistence use, some of which is provided by projects like this one. The Alaska Boards of Fisheries and Game use the harvest and other data to identify trends in local subsistence activities, and to evaluate proposals for regulatory changes. Communities, fish and game advisory committees, regional advisory councils, and individuals use the data to argue for changes to the regulations that would benefit their interests.

Section 809 of ANILCA authorizes the Secretary of the Interior to enter into cooperative agreements or otherwise cooperate with other Federal agencies, the State, Native Corporations, and other appropriate persons and organizations to effectuate the purposes and policies of Title VIII of ANILCA. Section 812 of ANILCA directs the Secretary, in cooperation with the State and other appropriate Federal agencies, to undertake research on fish and wildlife and subsistence uses on the public lands; seek data from, consult with and make use of, the special knowledge of local residents engaged in subsistence uses.

The project was planned in phases. In phase 1, researchers administered a comprehensive survey in the study community, analyzed the results, prepared this summary report for the community, and entered the results in the ADF\&G Community Profile Database. Phase 2, as yet unfunded, would conduct an analysis of the production and distribution of wild foods in the study community, and produce a draft report of findings. Phase 3, also unfunded, would fund a technical paper summarizing the harvest and producer analyses conducted in Phases 1 and 2. Progress through the phases is dependent upon the availability of funding and progress through the previous phase or phases.

## Purposes and Objectives

by Residents of Shungnak, Alaska, 2002

Under the cooperative agreement between the Na tional Park Service and the Alaska Department of Fish and Game, the purposes of this project were to:

- Document the demography, economy, harvest, and distribution of wild foods in one community in northwest Alaska;
- Continue to demonstrate the feasibility of a cooperative, community-based harvest reporting system;
- Work cooperatively with Alaska Native organizations that will employ local researchers to help collect subsistence harvest information; and
- Provide opportunities for community and regional involvement in harvest reporting and wildlife management.
The objectives of this project were to:
- Publish a summary report of selected findings (this report);
- Enter the survey data into the Community Profile Database maintained by the Division of Subsistence;
- Conduct additional analyses of food production and distribution networks, and of other social networks; and
- Publish a final report on the wild food production and distribution system, including social networks, in Shungnak in 2002.

## Literature Review and Rationale

Socioeconomic information is an important tool in the management of fish and wildlife resources, and especially subsistence uses of those resources. In 2002, comprehensive baseline harvest surveys were available for only four of the Northwest Arctic Borough's eleven communities (Deering, Kivalina, Kotzebue, and Noatak). Partial surveys - such as for salmon, large mammals, and migratory birds - existed for several other communities (Georgette et al 2003, Georgette 2000, Georgette 1999). Most of the communities lacked comprehensive socioeconomic data.

Previous research in the Kobuk area has been primarily ethnographic. Foote's recordings with Robert Nasruk Cleveland were the basis for an extensive collection of Kuuvanmiut legends (Cleveland 1980). NANA Elder's conference recordings were the

## Introduction

basis for a series of books published by the school district, documenting community histories and traditional stories (Lee et al 1990, Lee et al 1992, Mendenhall et al 1989). Kuuvaymiut Subsistence provided an encyclopedic study of Kobuk River subsistence practices in the 1970s, but no information about actual harvests (Anderson et al 1998). Nelson (1983), Giddings (1956, 1961, 1985), Ray (1975, 1983, 1984), and Burch (1975, 1980, 1984, 1988) have been the primary contributors to the ethnographic portrait of northwest Alaska Inupiat in general. Burch (1998a, 1998b) has described the Kuuvaum Kaŋiaġmiut in particular.

Burch, Jones, Loon, and Kaplan raised questions about the genesis of the Kuиvaum Kaךiagmiut (Burch et al 1999). They proposed that the Kuuvaum Kayiagmiut were a Koyukon Athabaskan society as recently as 1850, and were assimilated rapidly and peacefully into Iñupiaq Eskimo society between 1860 and 1880. Their theory is based on place name data, and on early ethnographic observations by Nelson (1983), Stoney (1900), Curtis (1930), Sun (1985), and others. The ethnogenesis theory was not widely accepted among contemporary Kuuvaum Kajiagmiut themselves. They thought the upper Kobuk may have been inhabited by itkillich ("Indians"), but they accepted the conventional view that Iñupiat pushed them out of the upper Kobuk. Kuиvaum Kayiaġmiut legends abound with stories of wars with Indians, which tended to support the conventional view.

The earliest written accounts of life on the upper Kobuk River date from 1884 and 1885, when Cantwell $(1887,1889)$ and Stoney (1900) conducted separate explorations of the region. Stoney's party spent the winter of 1885-86 living in a log cabin at the mouth of Cosmos Creek, about 10 miles below the community of Shungnak. Cantwell's and Stoney's accounts both provide views of the Kuuvaum Kayiaġmiut in a near pre-contact status. Stoney and his men traveled widely, into the Noatak valley and as far north as Point Barrow, providing an extensive record of conditions at the time.

The next accounts of life on the Kobuk date from 1900 , when an estimated 1,000 gold prospectors
spread out across the valley. Roberts' history of the Friends Church provides considerable detail from the missionaries' perspective (1978). Other accounts, such as those by Grinnell (1901) and Oman -- although focused on the central and lower Kobuk valley -- are useful in understanding conditions on the upper Kobuk in the early twentieth century.

The first formal ethnographic research in the area occurred in the 1940s, when archeologist J. Louis Giddings floated down the Kobuk River, and encountered Henry Stocking's family at the confluence of the Mauneluk and Kobuk rivers. His work continued in the area until his death in the 1960s. Giddings published accounts of Kuuvaum Kaŋiaġmiut life as recalled by four respondents, including a short account by Mike Qakiq Commack, who lived at the confluence of the Pah and Kobuk rivers (Giddings 1961), and an ethnographic portrait of the Kuиvaum Kaŋiaġmiut (Giddings 1956).

Georgette and Loon have documented contemporary subsistence practices, including those for brown bear and Dall sheep (Loon and Georgette 1989, Georgette and Loon 1991). Conflicts between local and non-local residents over fishing also have been described (Georgette and Loon 1990). Contemporary life on the upper Kobuk has been described in a series of popular and insightful accounts by an Ambler teacher, Nick Jans $(1994,1996)$.

Of all observers, Giddings was especially well situated to document conditions in the early $20^{\text {th }}$ century. But he understandably was interested in documenting pre-contact conditions while knowledgeable informants were still alive. Magdanz conducted a series of oral history interviews with elder Shungnak respondents, documenting patterns of settlement and land use in the early twentieth century (Magdanz 2002). Magdanz' work and the NWAB School Districts work filled some, but by no means all, of the gaps in the $20^{\text {th }}$ century history of the region.

This study provides the first statistical report on the full range of fish, wildlife, and plant harvests for an upper Kobuk River community. It also provides social and economic data, and social network data that have not been gathered previously.

The Subsistence Harvests of Wild Foods

## Methods

This project used a comprehensive household survey to gather information about social and economic conditions in Shungnak during calendar year 2002. The survey asked the head or heads of each household questions about each household member's relationship to the head, age, birthplace; about the household's fish and wildlife harvests; about who harvested, processed, and distributed the wild food used by the household; about each household member's jobs and earnings; and about other income received by the household. Researchers attempted to survey all occupied Shungnak households. Surveys were completed for 51 of 54 households (a 94.4 percent sample).

The principal investigator was James Magdanz, a subsistence resource specialist with the Division of Subsistence of the Alaska Department of Fish and Game who has worked for the Division in northwest Alaska for 20 years. He was assisted by Ron Paciorek, a Division of Subsistence analyst programmer from Anchorage, Eileen Devinney, a cultural anthropologist with the National Park Service in Anchorage, and Linda Lee, the administrator of the Shungnak IRA. Robert Walker, who manages the Division of Subsistence's data management program, directed data analysis.

The survey instrument was based on a standard survey developed by the Division of Subsistence for similar studies in Alaska in the 1980s and 1990s. The instrument collected information from each household on demography, wild food harvests, subsistence and household support obtained through social networks, household member employment, and household income. The Shungnak survey is attached as Appendix 2.

The demography section included questions about the gender, kin relationships, age, birthplace, education, and ethnicity of each household member. The harvest section asked which wild foods were used and harvested, and how much was harvested
by the household. The harvest section included 66 locally available species or species groups (e.g. berries). It also included 19 non-local species, such as seals, that were expected to be obtained through sharing, barter, and customary trade.

The employment section asked respondents to list each job held by each member of the household and, for each job, the months employed, the schedule worked, and the amount earned in the study year. A final page asked about other sources of household income, such as the Alaska Permanent Fund Dividend, social security, and other transfer payments.

Social network questions appeared throughout the survey. Near the beginning of the survey, respondents were asked, "Who helped your household with subsistence," and "Who helped your household in other ways?" After each category of resources (e.g. salmon, whitefish, birds), respondents were asked who harvested, processed, or distributed 14 categories of wild foods their household used. Near the end of the survey, respondents were asked who provided hunting and fishing information to their household, and who made hunting and fishing decisions for their household. Finally, they were asked who supported their household in other ways, such as child care and equipment maintenance. Similar questions were asked in a previous study of subsistence food production in the northwest Alaska communities of Wales and Deering (Magdanz et al 2002).

Confidentiality was maintained through the use of identification codes. Households and individuals were assigned numerical codes before the survey began. Code sheets were collected by the principal investigator after survey administration was completed, and remained in his custody. Codes sheets did not accompany the surveys when they were submitted for analysis.

Confidentially was especially important with the social network data, which identified people who provided subsistence and household support

## Methods

to the respondent households. Again codes, not names, were entered on the survey instruments. When a person from outside the community was named in response to a social network question, his or her name was entered on a tear-off sheet and assigned a unique household-specific code on the spot. Non-local individuals who were named by several households usually had different codes on each surveys. The principal investigator collected all the tear-off sheets after survey administration, and recoded non-local individuals with uniform and unique codes.

For this report, the focus of data analysis was the demographic, harvest, and economic data. Preliminary analyses of social network data were conducted to evaluate the quality of the data set. More thorough analysis of network data was planned for the second phase of this project.

## Procedures

In September, 2002, researchers attended a meeting of the Shungnak IRA Council, handed out copies of the draft survey instrument, and discussed the project goals. In November, 2002, the council adopted a resolution supporting the research (Appendix 1). Subsequently, researchers worked with the IRA staff to prepare an updated household-by-household census of the community. The IRA also began advertising for contractors to administer the survey. Shungnak residents Caroline Tickett, Eileen Tickett, Gary Tickett, and Robert Waters were selected to work with the project.

On January 30, 2003, Magdanz and Paciorek traveled to Shungnak. They held a public meeting in the high school gymnasium and discussed the project. The meeting was attended by about 30 people, who were asked to complete a two-page individual questionnaire. On January 31, Eileen Devinney traveled to Shungnak. On January 31 and February 1, Magdanz conducted two-day orientation meeting in the Shungnak National Guard armory, attended by all the local and non-local researchers. During the orientation, researchers verified lists of households and residents, reviewed species lists, reviewed procedures for coding producers, and practiced survey administration on one another. At the end of the orientation, each researcher selected a group of households to survey, and began making
appointments by telephone and in person to conduct the surveys.

Surveys all were conducted in person, almost always in the respondent's home, at a time selected by the respondent. Surveys were administered to either the male or female head of household, who was asked to provide information about the household as a whole. Sometimes, both heads of household or other family members would assist the respondent by providing information. Surveys required from 15 minutes to 3 hours and 15 minutes (in one case) to complete. Average survey administration time was 1 hour and 15 minutes. Survey administration began the evening of February 1, 2003, and continued through February 8, 2003. At the conclusion of survey administration, researchers convened again for project evaluation meetings. They discussed the performance of the instrument, subjectively assessed the quality of the data gathered, and made suggestions to improve the survey process in the future.

After survey data had been analyzed and summarized, a draft copy of this report was provided to the Shungnak IRA Council, and circulated to project cooperators for review. In June 2004, the IRA Council approved the draft report without changes. A final report was prepared and printed.

## Limitations and Assumptions

The harvest survey collected information on subsistence activities during the calendar year 2002. This assumed that respondents could remember their important activities during the past year. To minimize recall problems, surveys were conducted with household heads on the assumption that household heads were most likely to be aware of all household members' activities. Respondent recall bias was not expected to change significantly over time or from community to community. It was not expected to affect comparisons of data from this study with other studies employing similar methods.

One function of the agencies involved in this study was to enforce fish and wildlife regulations. None of the researcher in this project was involved in enforcement activities. Nonetheless, some residents of northwest Alaska perceived any wildlife agency employee as a "game warden." The week before the study, a Shungnak elder killed several caribou just behind Shungnak. The animals were close to his
home, and he didn't take his hunting pack, which carried his lifetime hunting license. A game warden was in the area, saw the kill from the air, landed on the elder, and gave him a warning for not having his license on his person. Another hunter in Shungnak was also contacted by a warden about the same time, though the details of that encounter were less clear. The elder agreed to be surveyed for this project, and was surveyed by Magdanz, the project leader. The other hunter declined to be surveyed.

Some respondents were reluctant to provide information about personal and household incomes, in particular about earned income. One of the researchers was personally reluctant to ask respondents about employment and income. The result, unfortunately, was that employment and income data were missing for 42 percent of the individuals in the sample.

Standardization in data collection procedures was important because seven different people gathered data for this project. The principal investigator was present throughout the administration of the survey and administered surveys himself. Standardization and quality control were accomplished through the initial orientation process, daily reviews of surveys as completed, and post-administration review of all surveys. The principal investigator coded all of surveys for data entry.

The principal analyst-programmer left the Division of Subsistence after data entry was completed, but before data analysis was completed. Final analyses for this summary report were conducted by the Division's senior analyst-programmer and by the principal investigator. The production of final SPSS system files and the addition of these data to the Community Profile Database were delayed by this change of personnel.

## Data Analysis

Survey data were entered twice, and compared programmatically for inconsistent data entry. Double data entry ensures more accurate transfer of information from the coded survey forms into the database. Data did not pass to the processing phase until inconsistencies between the twice-entered data set were eliminated. Range and logic checks were also performed on the data to highlight potential data inconsistencies. Identified records were verified for accuracy by consulting the original survey forms.
by Residents of Shungnak, Alaska, 2002

Subsistence harvest estimates may be calculated based upon the application of weighted means (Cochran 1977). These calculations are standardized methods for extrapolating subsampled data.

The estimated sample mean take per village is:

$$
0_{S}=\sum_{\mathrm{i}=1}^{\mathrm{K}} \mathrm{~N}_{\mathrm{i}} \mathrm{O}_{\mathrm{i}} / \mathrm{N}
$$

Where:
$\mathrm{i}=$ strata variable
$1-\mathrm{K}=$ the numbered designation of strata i
$\mathrm{N}_{\mathrm{i}}=$ strata i population
$0_{i}=$ mean harvest per household within strata $i$
$\mathrm{N}=$ village population

The estimated village sample variance is

$$
\left.\operatorname{Var}\left(0_{\mathrm{S}}\right)=\sum \mathrm{N}_{\mathrm{i}}^{2} \operatorname{Var} \underset{\substack{\mathrm{i}=1 \\ \mathrm{i}=1}}{\mathrm{~K}}\right)\left(\left(\mathrm{N}_{\mathrm{i}}-\mathrm{n}_{\mathrm{i}}\right) /\left(\mathrm{N}_{\mathrm{i}}-1\right)\right) / \mathrm{N}^{2}
$$

Where:
$\mathrm{n}_{\mathrm{i}}=$ sampled households in strata i
Var $=$ variance

The estimated standard error (SE) of $0_{S}$ is the square root of $\operatorname{Var}\left(0_{S}\right)$.

The village harvest can be estimated by

$$
\mathrm{T}_{\mathrm{s}}=\mathrm{N} 0_{\mathrm{S}}
$$

with estimated standard error

$$
\operatorname{SE}(T)=N \cdot S E\left(0_{S}\right)
$$

For the Shungnak project, a single sampling strata (i.e., an attempted census which was considered equivalent to a simple random sample) was used for the community.

Summary statistics other than harvest estimates were calculated with the Statistical Program for the Social Sciences (SPSS).

Social network data were analyzed using SPSS and Ucinet, a program designed for social network analysis (Borgatti et al 2002). Each response to a social network question was entered as a separate record in SPSS. Each record included variables identifying the respondent household, the role of the person (e.g. harvester, processor, child care
provider), and the identification code of the person providing the food or support. These variables did not measure the amounts of food or other support provided. Respondents were asked how much their household harvested, but were not asked to account for those harvests on a person-by-person basis.

The SPSS crosstabs procedure was used to cre-
ate a 51-by-51 matrix of Shungnak households, in which each cell was a count of the number of times a particular household was identified as a source of support for each respondent household. The matrix, sorted by household number, appears in Appendix 2. The matrix was read into Ucinet, normalized, and displayed in NetDraw.

The 51 households surveyed in Shungnak reported harvesting 143,441 edible pounds of wild foods between January and December, 2002. The average harvest per household was 2,813 pounds; the average harvest per person was 610.4 pounds. Expanding for three unsurveyed households, Shungnak's estimated total harvest of wild foods in 2002 was 151,911 pounds ( $\pm 8.7$ percent).

Caribou accounted for the largest harvest of a single species, with 403 animals taken for a total harvest of 54,864 pounds, 36 percent of the total community harvest of wild foods (Figure 3-1). The largest harvest of a species category, though, was of fish. Fish contributed 84,340 pounds, or 54 percent of the total community harvest. A majority of the fish were whitefish, 47,030 pounds, or 31 percent
of the total. Salmon contributed 22,942 pounds, or 15 percent of the total.

This chapter summarizes some findings from the household survey, including demographic characteristics, responses to harvest assessment questions, harvest estimates, employment, income, and social networks. Harvest numbers are expanded estimates. More detailed tables of results appear in Appendix 2. Additional information from this survey will be available in the Division of Subsistence Community Profile Database.

## Demographics

The 51 sampled households included 235 people, of whom 221 ( 94 percent) were Alaska Native. The population included 103 males ( 44 percent) and 132

Figure 3-1. Composition of subsistence harvest, Shungnak, 2002. Fish accounted for 54 percent of the total estimated harvest in Shungnak in 2002, while land mammals contributed about 41 percent. Caribou contributed more than any other single species, accounting for 37 percent of the total harvest, followed by whitefish with 31 percent.

## Findings

Figure 3-2. Population profile by age and sex, Shungnak, 2002. (Figure does not include 9 males with missing ages.)
females ( 56 percent) (Figure 3-2). The project's presurvey census of the community estimated 5 males and 8 females in the three unsurveyed households, for a total population of 248 people in 54 households. As a comparison, the 2000 census reported 256 people in 56 households.

In the early 1990s, Hamilton and Seyfrit observed higher emigration rates for young women in small communities in the Northwest Arctic Borough. They found that in the 15-39 age group there were 113 men for every 100 women, and in Shungnak the ratio was 148:100 (Hamilton and Seyfrit 1993:261-262). The 2000 census reported a 103:100 ratio in Shungnak. By 2002, the ratio had reversed, to 78:100 for all ages, and to 90:100 in the 15-39 age group.

Two thirds of the population was born in Shungnak, 149 of the 221 residents ( 67 percent). Only slightly fewer reported Shungnak as their mother's natal community ( 62 percent) or as their father's natal community ( 63 percent). Consistent with these reports, 62 percent said they had never lived in any community other than Shungnak.

Other than Shungnak, the community of birth reported most often was Selawik, named by 6.8
percent of the current residents. A similar proportion ( 6.3 percent) reported birthplaces outside Alaska; these were mostly teachers. Most of the remaining residents were born in other rural northwest communities; most of the Northwest Arctic Borough communities were represented. Only 4.1 percent reported Anchorage or Fairbanks as their birthplace.

Level of formal education was reported for 219 respondents ( 93 percent of the population). Of those 219 people, 10 percent reported formal education beyond high school. Twenty six percent reported having completed high school or earned their G.E.D. Twenty two percent reported some formal education, but did not earn a high school degree. The remaining 42 percent were still continuing their education.

On the average, residents had lived in Shungnak for 22.7 years. Considering only Alaska Natives, average residency was 23.9 years, compared with 2.7 years for non-Alaska Natives.

Wolfe has categorized households by social type based on the age of household heads (Magdanz et al 2002:60). Developing households were those in which both heads were 39 years old or younger. Mature households were those with the oldest head

* Survey also asked about firewood. This table includes only edible species.
between 40 and 59 years old. Elder households were those in which one or both heads were 60 years old or older. Single person households were grouped into a single category regardless of age.

In Shungnak in 2002, there were 11 developing households ( 22 percent), 23 mature households ( 45 percent), 11 elder households ( 22 percent), and 6 single-person households ( 12 percent).

## Harvests

The household survey collected information about the harvest and use of 85 different edible wild food species or categories of species, and about the harvest of firewood. Respondents were asked whether their household used, attempted to harvest, or harvested each resource during the study year. For each resource, they were asked if their household received the resource from another person or household, and if they gave away each resource to another person or household

If they harvested a resource, they also were asked how much they harvested and, for fish, how much was harvested by each type of gear (seine, gill net, etc.). Finally, for eight categories of wild foods, they
were asked to compare harvests in the study year with harvests in the past, and to assess whether or not the study year's harvest was "enough."

This section summarizes the answers to these questions. The tables in Appendix 2 provide additional detail on responses to these questions for all 86 resources.

Table 3-1 and Table 3-2 summarize responses to the harvest questions on the survey. Table 3-1 aggregates responses into five categories, while Table 3-2 summarizes responses for each resource. In Table 3-2, resources are ranked in descending order of edible pounds harvested within each category.

Of the 85 edible wild foods on the survey, 19 species were not locally available, but were likely to be obtained through sharing, barter, or trade. These included whales, seals, marine fish, and shellfish. Of the 66 species locally available for harvest, 61 were reported as used, 56 were reported as attempted to harvest, and 49 were actually harvested (Table 3-1).

The most commonly used species was caribou, reported as "used" by 98 percent of the households and harvested by 67 percent (Table 3-2). Berries

| NOTES: Respondents were asked to report the number of fish and wildife harvested, except for plants which were reported as gallons. For species harvested in large numbers, such as whitefish, harvest were reported as washtubs, buckets, and sacks. Unorthodox units were converted to numbers using a species-specific conversion table for unorthodox units. Harvest numbers were converted to edible pounds using standard conversion |  |  |  |  |  |  |  |  |  |  |

## Findings

were used by 94 percent of the households, and harvested by 84 percent. Humpback whitefish and sheefish were used by 84 percent of the households, and harvested by 65 percent.

Eight species accounted for 95 percent of the total harvest. After caribou, the seven species contributing the most to Shungnak's harvests were: humpback whitefish, ( 40,615 pounds), chum salmon ( 22,858 pounds), sheefish ( 11,111 pounds), moose (5,696 pounds), berries ( 2,374 pounds), and northern pike (1,974 pounds). No other species contributed more than 1,000 pounds to the total.

In many of Alaska's riverine communities, salmon are the dominant species. That is not the case in Shungnak, where whitefish (humpback whitefish, round whitefish, broad whitefish, least cisco, and sheefish) play a major role. In 2002, the combined whitefish harvest ( 58,141 pounds) was more than two and a half times that of the salmon species $(22,942)$. Most whitefish were taken in the fall, and air dried. Broad whitefish were taken in November, most commonly, and were stored frozen in the round. Sheefish were taken in the summer and fall and usually were stored frozen.

Seine nets, used extensively for harvesting humpback whitefish in the fall, accounted for 74 percent of the whitefish harvests, by weight. Rods and reels, used for harvesting sheefish during their upstream migration in July, accounted for 48 percent of the sheefish harvest and 10 percent of the whitefish harvest. Gill nets accounted for only 13 percent of the whitefish (sheefish caught in salmon nets in summer and fall, broad whitefish caught with gill nets set under the ice in November, and humpback whitefish caught in gill nets in the spring).

For salmon, though, gill nets were more productive, accounting for 73 percent of the salmon harvest. Seines took 25 percent of the salmon, by weight. For all the rest of the fish, gills nets accounted for 55 percent of the harvest, followed by rods and reels with 21 percent, and jigging through ice (for burbot, primarily with 17 percent.

Caribou were by far the largest source of red meat for Shungnak, accounting for 90 percent of the large land mammal harvest. Moose accounted for 9 percent of the large land mammal harvest. Bear contributed less than 1 percent.

Relatively few furbearers were reported on the
survey, seven wolf and no wolverine. Although lynx populations were near record highs in 2002, only three lynx were reported. The data suggested that Shungnak residents were harvesting furbearers for local use primarily, and not for the fur trade. Anecdotal information suggested that furbearer reports may have been incomplete.

One of the most commonly used species ( reported as "used" by 63 percent of the households) was a species not locally available, bearded seal. Bearded seal was harvested by only one household (which had relatives living in Shishmaref). Other households obtained their bearded seal meat and oil through sharing, barter, or customary trade. Dried bearded seal meat in oil is a highly valued traditional food, nigizipiaq.

The waterfowl harvest ( 2,292 pounds) was approximately equally apportioned among Canada geese, white-fronted geese, and ducks (pintail, mallard, and long-tailed ducks). The only resident bird harvested in any quantity, ptarmigan, accounted for 264 pounds.

The survey asked about berries in the aggregate, and did not collect amounts by species. Respondents most commonly mentioned harvesting blueberries, cranberries, and salmonberries. The greens harvest included willow leaves, wild rhubarb, and sourdock. The root harvest was Eskimo potato.

Twelve species were reported as used, but not harvested. More than half the households ( 53 percent) reported using whale, either bowhead (47 percent) or beluga ( 18 percent), or both, all obtained through sharing, barter, or customary trade. About half of the used but not harvested species were reported by only one household.

## Harvest Comparisons and Assessments

Responses to the comparison and assessment questions indicated that the harvest in 2002 was generally better than it had been in the past (Table 3-3). For seven of the nine categories, at least 50 percent of the respondents said their household had harvested the same as or more than they had in previous years. Harvest assessments were most positive for large land mammals, with 49 percent of the households reporting more harvested, and 31 percent reporting the same harvests as in the past. Forty nine percent of the households also reported harvesting more fish

## Findings

(other than salmon or whitefish), while 18 percent reported harvesting the same. Whitefish and salmon harvests were also good, with more than two thirds of the households reporting harvests better than or similar to harvests in the past.

Harvest assessments were most negative for small land mammals and for marine mammals. Twenty four percent harvested more small land mammals and 20 percent harvested the same amounts, while 43 percent reported harvesting less. The marine mammal assessment was interesting. Seventy five percent said their marine mammal harvests were "less" than in the past. Given Shungnak's location 150 miles from the ocean, one would have expected at least some households to report "never harvest" for marine mammals, but none did.

Respondents also were asked whether their households had been able to get "enough" of the same nine different categories of species. Responses were decidedly pessimistic; on average two thirds of the responses were "No." Eighty percent of the households said they had not been able to get enough large land mammals, although 80 percent of the households also said they had harvested either more or the same amount of large land mammals in the past.

## Jobs and Income

Of the 130 adults in Shungnak in 2002, 43 adults ( 33 percent) reported holding at least one job at some
time during the study year, while 17 adults ( 13 percent) reported being retired (Table 3-4). Fifteen (12 percent) considered themselves to be unemployed. However, the jobs and income data were the least complete data set on survey.

At least one of the local survey workers seemed very reluctant to gather job and income data, and some respondents were reluctant to provide it. There was no employment data for 55 adults ( 42 percent), which was unfortunate. Nonetheless, average, minimum, and maximum employment values were still informative.

Table 3-4 summarizes these values for men, women, and Alaska Natives. The total income reported from employment in Table 3-4 should be considered as incomplete. Respondents reported holding, on average, 1.2 jobs per person, with a maximum of 4 jobs. Many respondents held seasonal jobs, as the average months worked was only 4.3 months per year.

Alaska Native residents accounted for 82 percent of the months worked, but only 71 percent of the earned income. This reflected the higher incomes earned by teachers, who worked full time and (in many cases) had advanced college degrees, including one Ph.D. High wages were also paid on some construction jobs, but these tended to be more seasonal than education jobs.

The school in Shungnak was funded by the Northwest Arctic Borough, through tax receipts

## Findings

from the Red Dog Mine near Kivalina and through state and federal education funding. Public funds also were the primary support for jobs in the City of Shungnak and the Native Village of Shungnak. The Alaska Village Electrical Cooperative employed several part-time people to operate and maintain the
electrical generation system. The Alaska Native Industries Cooperative Association employed several people in the local Native store.

During the study year, seasonal work was available during the construction of seven new houses. That project was funded by the Northwest Iñupiat

NOTE: The survey included two general questions: "Who helped your household with subsistence," and "who helped your household in other ways?" Responses to these general questions are listed in this table as "Network Member."

Housing Authority, based in Kotzebue.

## Social Networks

Social networks are an important feature of the subsistence economies in many, if not all, northwest Alaska communities. People work together extensively to harvest, process, and distribute wild foods. Magdanz, Utermohle, and Wolfe described cooperative food production networks for Wales and Deering (2002). This study used a similar, but expanded, survey instrument to document 16 different subsistence and household support roles in Shungnak. The survey instrument also included a new page to record people who provided subsistence or household support to Shungnak households, but
did not live in Shungnak.
Table 3-5 summarizes responses to the social network questions. Each cell in the table counts an instance of subsistence or household support, in which one person was named for one activity by one household. For example, survey households in Shungnak reported 390 instances of wild food harvesting by someone who lived in the respondent household. This could have been a head of a household harvesting caribou, or a daughter in a household harvesting salmon.

The 51 survey households reported 4,350 instances of subsistence or household support in the study year. Residents of Shungnak were named for 4,101 instances ( 94 percent), and residents of

other communities were named for 249 instances (6 percent).

Wild food harvesting, processing and distribution accounted for 2,521 instances ( 58 percent). Hunting and fishing information and decision making accounted for 366 instances ( 8.6 percent).

Fishing decisions were most often made by someone not living in the respondent household (58 percent), while hunting decisions were most often made by someone in the respondent household ( 84 percent). Most likely, this reflects elder women's important role in organizing fishing, especially fishing for whitefish and salmon from the fish camps. Hunting was a more autonomous activity conducted primarily by men. Survey responses suggest that hunters were making individual decisions about when and where to hunt. Nonetheless, hunters relied extensively on individuals outside the respondent household for information (66 percent).

The survey included two general social network questions: "Who helped your household with subsistence," and "Who helped your household in other ways?" These two questions accounted for 795 responses ( 18 percent of the total). Researchers included these questions to assess whether two simple questions could describe subsistence and household networks reasonably well. Researchers’ general impression during the survey administra-
tion was that these questions worked well for some households but not for others, and that respondents found them redundant (which they were). Further analysis could determine how successful these questions were.

Residents of Kotzebue were named most frequently as sources of subsistence and household support (77 instances, or 1.8 percent of the total). Residents of nearby Kobuk were named 40 times, and residents of Barrow were named 22 times. Barrow residents were named for harvesting, processing, and distribution of bowhead whale. Residents of other communities were named most often as distributors (that is, sources) of wild food. One hundred of 550 distribution instances were for people outside Shungnak.

Most of the social network questions on the survey asked respondents to identify people who provided subsistence or household support to the respondent household. One series of questions, though, asked respondents to identify people living outside Shungnak who received wild food from the respondent household.

Table 3-6 summarizes the types and destinations of wild foods sent from Shungnak to other communities. Caribou was named most often, followed by sheefish and whitefish. Kotzebue was named most often as the destination. Kotzebue also was named

Figure 3-3. Preliminary social network diagram, Shungnak, 2002. In this NetDraw graph, each circle represents a household. Connecting lines represent the flow of support from one household to another. The contrasting circles and lines on the left side identify an extended family organized around an active elder couple and seven related households.
most often as a source of wild food, so some of these exchanges may be reciprocal. The data include enough data to identify reciprocal exchanges, but that was not done for this stage of analysis.

Shungnak's social networks can be depicted in a diagram, in which each household is a node connected to other households. In the diagram, the location of households and the distance of each household from other households are related to the
number of connections each household has with all other households in the sample.

Figure 3-3 is a preliminary diagram of Shungnak's social networks, created with Ucinet and NetDraw. It includes all types of subsistence and household support. The social network data indicated that households in Shungnak cooperated extensively. Cooperation was most evident in the production and distribution of wild food, but was present for most other types of household support activities.

Standardized comprehensive subsistence household surveys have been conducted in rural Alaska communities since the early 1980, including 18 communities in the Northwest Arctic, North Slope, and Koyukuk River regions of Alaska. Limited subsistence surveys (e.g. for salmon or waterfowl) have been conducted in most rural communities. This chapter compares results from Shungnak in 2002 with surveys in other communities and with
past surveys in Shungnak.
This was the first comprehensive subsistence survey conducted in Shungnak, and the first ever conducted for any of the five Kobuk River communities. Previous surveys in Shungnak have documented harvests of salmon from 1994-2002, waterfowl in 1993, and large land mammals in 1998 (Georgette et al 2003, Georgette 2000, Georgette 1999).
Figure 4-1 shows estimated harvests for Shungnak

Figure 4-1. Comparison of estimated subsistence harvests by community. Shungnak's estimated subsistence harvest of 610 pounds per person was comparable to the average 674 pounds per person estimated for other northwest and Arctic Alaska communities, but less than estimates for nearby interior communities like Allakaket, Hughes, and Huslia.
by Residents of Shungnak, Alaska, 2002

Figure 4-2. Comparison of estimated subsistence harvests of fish. Subsistence harvests of whitefish, salmon, and sheefish have been documented in Shungnak by annual household surveys. Harvests of salmon and sheefish documented by this study were comparable with previous estimates, while the whitefish harvest was twice the average of past years.
and eight other Northwest Arctic communities, five North Slope communities, and four Koyukuk River communities. The northwest Arctic and north slope community harvests, with the exception of Barrow, ranged from 461 to 890 pounds per person. Koyukuk River community harvests, with the exception of Bettles, were higher, ranging from 900 to almost 1,500 pounds. The Koyukuk estimates, though, are older, dating from the early 1980s.

Shungnak's estimated per capita harvest of 610 pounds was near the middle of range for northwest Alaska communities. It was similar to harvests estimated for Brevig Mission (579 pounds), Golovin ( 605 pounds) and Kotzebue (593 pounds).

## Comparisons with Previous Shungnak Surveys

Several harvest surveys have been conducted in Shungnak in the past, dating back at least to the studies conducted during the Alaska Native land claims settlement process. However, early surveys lacked information (sample size, for example) needed to compare them with contemporary surveys. The first statistically sound survey conducted in

Shungnak probably was one conducted by Maniilaq Association and the ADF\&G Division of Subsistence in 1994, documenting waterfowl harvests in 1993. The same two organizations also conducted a survey in 1999, documenting large land mammal harvests in 1998. ADF\&G also has conducted salmon surveys throughout northwest Alaska each year since 1994. The "salmon survey" also has gathered information about sheefish and whitefish harvests in Shungnak.

Figure 4-1 compares data from the annual salmon surveys for 1994 through 2001 with this survey data for 2002. Salmon harvests trended downward during the period; the 2002 harvest of 3,810 salmon was similar to harvests in the previous three years, but 46 percent below the average harvest during the previous eight years, 5,556 salmon. The sheefish harvest in 2002 was the second highest harvest reported in seven years of surveys, 2,020 sheefish compared with an average of 1,328 in the previous six years.

The harvest of whitefish estimated in this study was by far the largest reported in six years of surveys. Although whitefish numbers always have

exceeded salmon and sheefish combined, in 2002 Shungnak residents harvested four times as many whitefish as they did salmon and sheefish. One reason for the large difference was low water in 2002, which made seining easier and may have concentrated whitefish in fewer and smaller areas.

Whitefish conversion factors used in the northwest salmon survey also were revised before this study, increasing the estimated number of fish per tub by almost two times (Georgette 2004).

Table 4-1 compares data from previous land mammal and bird surveys for Shungnak. Declines

## Discussion

were noted for black bear, caribou, and moose compared with 1998; the change in brown bear harvests was not statistically significant. Likewise, declines were noted for many bird species, notably Canada geese, scaup, scoter, and ptarmigan.

In reviewing the findings, researchers thought that responses to the comparison and assessment questions seemed inconsistent. While most households reported harvesting more or the same amount of most species, most households also reported not getting enough. Researchers did not believe Shungnak's overall harvests had been depressed in recent years.

The comparative data, however, tended to support respondents' assessments. The 2002 salmon harvest was substantially larger than in the previous two years, but still well below harvests documented in the mid 1990s (Georgette 2003). The 2002 caribou harvest, while substantial, was 28 percent less than the harvest estimated for 1998 (Georgette 1999).

Another explanation for the apparent inconsistency of the two responses was that respondents considered each species within a category. For example, some respondents commented that they could never get "enough" bowhead whale muktuk or "enough" seal oil or "enough" Dall sheep, resources which were scarce in Shungnak. While overall harvests might have been more or the same for a species category, the harvest of one particular species in that category might have been deficient, leading to a "no" response to the question.

## Comments on Harvest Composition

Most northwest and Arctic communities depend substantially on three resource categories: fish, land mammals, and marine mammals. Shungnak depended substantially on only two: fish and land mammals. In terms of composition, Shungnak's harvest was more similar to nearby interior Alaska communities.

Unique among all the surveyed communities,

Shungnak depended substantially upon whitefish. In the four nearby fish-dependent interior Alaska communities, on the one hand, salmon comprised from 61 to 94 percent of the total fish harvest. In Shungnak in 2002, on the other hand, salmon comprised only 27 percent of the total fish harvest.

The dependence on whitefish certainly was related to their abundance, but it may also be related other factors. Whitefish were available at a time of the year when they can be easily dried (fall) or frozen (winter). Whitefish also were available consistently, compared with other resources like caribou, moose, and salmon. Caribou populations are cyclical, and during periods when populations are low, caribou are not a reliable source of food. In the late 1970s, the caribou bag limit was one bull per year (compared with the current five per day). In the 1930s and 1940s, elders remember, Kobuk River people had to travel north to the Noatak valley to get caribou. Moose are relatively recent arrivals in the upper Kobuk River, having become abundant only in the latter half of the twentieth century. Both caribou and moose populations are expected to decline in the future, which would make Shungnak more dependent upon fish than it was in 2002.

Salmon stocks also tend to be cyclical. Upper Kobuk elders remember a period of poor salmon returns around 1950. In the late 1990s, salmon returns declined in the Kuskowkim, Yukon, and Norton Sound drainages. Kobuk River stocks have not declined to the same degree, but if they did, then whitefish would become a critical subsistence food resource for Shungnak.

Although some upper Kobuk residents do travel to the coast to harvest marine mammals, in the study year only 0.5 percent of Shungnak's harvest was marine mammals. In all the other northwest Arctic and north slope communities for which data are available, marine mammals comprised at least a fourth of the total harvest, by weight, and in some communities contributed much more than half.

## Appendix I: Resolution

# NATIVE VILLAGE OF SHUNGNAK <br> P.O. BOX 64 <br> SHUNGNAK, ALASKA 99773 <br> (907) 437-2163 Phone <br> (907) 437-2183 Fax 

Resolution 02-19
A Resolution in support of a comprehensive subsistence survey to be Conducted in Shungnak by the Native Village of Shungnak, the Alaska Department of Fish and Game, and the National Park Service.

WHEREAS: the Native Village of Shungnak is the governing body of the Village of Shungnak; and

WHEREAS: the Alaska Department of Fish and Game and the National Park Service Have responsibilities for managing the lands and resources that resident of Shungnak Use for subsistence hunting, fishing, and gathering; and

WHEREAS: participation in the project is voluntary, and person's names will not Be used in the survey reports; and

WHEREAS: local research assistants will be paid to assist in administering the survey; and

WHEREAS: the project will document the importance of subsistence harvests of fish and wildlife, so that traditional subsistence uses might be protected in the future.

NOW THEREFORE BE IT RESOLVED; that the Native Village of Shungnak hereby Supports the comprehensive subsistence harvest survey to be conducted in Shungnak.

FURTHER BE IT RESOLVED: that the Native Village of Shungnak will monitor the project in the Native Village of Shungnak.

## CERTIFICATION

This resolution was approved by a vote of 6 in favor, $\varnothing_{\text {against, and }} \oint_{\text {abstaining }}$.

HOUSEHOLD INFORMATION
ID \# OF PERSON RESPONDING TO SURVEY:
WHO WERE MEMBERS OF THIS HOUSEHOLD BETWEEN JANUARY AND DECEMBER, 2002?

WAS YOUR HOUSEHOLD'S SEASONAL PATTERN OF SUBSISTENCE ACTIVITIES BETWEEN JANUARY AND DECEMBER 2002 SIMILAR TO OTHER YEARS, OR DIFFERENT?
SIMILAR (1) DIFFERENT (0)

## NETWORK PILE SORT

IN THIS SURVEY WE OFTEN WILL BE ASKING, "WHO HELPED YOUR HOUSEHOLD?" TO KEEP TRACK OF PEOPLE WITHOUT USING NAMES, WE USE CODES WE ALREADY HAVE ASSIGNED CODES TO EVERYBODY IN SHUNGNAK.
WE HAVE ONE CARD FOR EACH HOUSEHOLD, WITH CODES FOR PEOPLE IN THAT HOUSEHOLD
BEFORE WE DO THE REST OF THE SURVEY, I WANT TO PULL OUT THE CARDS WITH THE PEOPLE WHO HALPED YOU.
BETWEEN JANUARY AND DECEMBER, 2002, WHO IN SHUNGNAK HELPED YOUR HOUSEHOLD WITH SUBSISTENCE? (FOR EXAMPLE, BY HUNTING, FISHING, PROCESSING, OR GIVING YOU WILD FOODS) PLEASE LIST THE MOST IMPORTANT PEOPLE FIRST.
TO KEEP TRACK OF PEOPLE WITHOUT USING NAMES, WE USE CODES
BETWEEN JANUARY AND DECEMBER, 2002, WHO HELPED YOUR HOUSEHOLD IN OTHER WAYS?
(FOR EXAMPLE, TAKING CARE OF YOUR CHILDREN, FIXING YOUR EQUIPMENT, CLEANING YOUR HOUSE, COOKING, BUYING GROCERIES) PLEASE LIST THE MOST IMPORTANT PEOPLE FIRST

NOTE: IF THE RESPONDENT NAMES PEOPLE WHO LIVE OUTSIDE SHUNGNAK, USE CODES FROM THE BACK PAGE OF THE SURVEY

## NON-COMMERCIAL FISHING: SALMON (CONTINUED)
